INDEX OF CONTENTS.

JULY TO DECEMBER, 1877.

A

ABERDEENSHIRE, measurements of trees 16, 435
 Abies Engelmanni, 42, 85, 117, 248;
 Menziesii Parryana, 85, 248
 Abutilon Darwinii tessellatum, 530;
 A. Lemoinei, 248, 777
 Acacia arabica, 369
 Acalypha macrophylla, 231
 Adelaide Botanic Gardens, 136
 Adiantum æmulum, 584; A. caudatum,
 777; A. Edgworthii, 632
 Adulteration of Seed Act, prosecutions
 under the, 688, 697, 720, 722, 784, 789
 Æchmea Veitchii, 632
 Æsculus parviflora, 653
 Aërides crassifolium, 20, 492; testacum,
 166; Wightianum, 166
 African Vegetation, Notes on, 460
 Agave, Mr. Baker's Synopsis of the
 Species of, 40, 136, 200, 264, 396, 490,
 556, 620, 682, 717, 748, 780, 807; key
 to the species, 808
 Agave albicans, 717; A. americana, 201;
 A. attenuata, 748; A. Bernhardii, 717;
 A. Botteri, 264; A. Bouchei, 717;
 A. brachystachys, 807; A. Brauniana,
 717; A. bromeliæfolia, 780; A. cali-
 fornica, 556; A. caribæa, 683; A.
 Celsiana, 620; A. chloracantha, 717;
 A. coccinea, 201; A. concinna, 113;
 A. Corderoyi, 398, 469; A. dasyliri-
 oides, 557; A. Decaisneana, 264; A.
 densiflora, 490; A. Ehrhenbergii, 620;
 A. Ellemetiana, 748; A. elongata,
 397; A. elongata var. sisalana, 397;
 A. excelsa, 397; A. ferox, 40; A.
 flaccida, 137; A. Galeottii, 40;
 A. geminiflora, 620; A. Gœppertiana,
 682; A. guttata, 808; A. Haselofii,
 683; A. horizontalis, 682; A. Houlettii,
 557; A. Humboldtiana, 682; A. Ixtli,
 397; A. Jacquini-
 ana, 264; A. kewensis, 683; A.
 laxa, 780; A. Laurentiana, 620; A.
 Lindleyi, 620; A. lurida, 264; A. ma-
 cracantha, 137; A. maculata, 807; A.
 Martiana, 683; A. Maximiliana, 201;
 A. melaëacantha, 620; A. mexicana,
 201; A. micracantha, 717; A. mira-
 dorensis, 31, 264, 659; A. mitis, 717;
 A. Muillmanni, 683; A. Newberryi, 557;
 A. oblongata, 903; A. Ofofayana, 620;
 A. Palmeri, 200; A. Parryi, 40; A.
 polyacantha, 490; A. potatorum, 40;
 A. pruriçosa, 748; A. pubescens, 807;
 A. pugioniformis, 780; A. Regelian,
 398; A. regia, 620; A. revoluta, 808;
 A. rigida, 397; A. rubescens, 780;
 A. rudis, 620; A. rupicola, 717; A.
 Salmeyckii, 490; A. Sartorii, 683; A.
 Scolymus, 40; A. Seemanniana, 40;
 A. serrulata, 780; A. Shawii, 241; A.
 Smitthiana, 682; A. sobolifera, 780;
 A. spicata, 781; A. striata, 556; A.
 striata var. echinoides, 556; A. striata
 var. recurva, 556; A. striata var.
 stricta, 556; A. Theometel, 200; A.
 Thomsoniana, 717; A. undulata, 808;
 A. utahensis, 137; A. variegata, 808;
 A. virginica, 807; A. viridissima,
 137; A. vivipara, 780; A. Wallisii,
 717; A. Warelliana, 264; A. Wis-
 lizeni, 40; A. yuccæfolia, 718
 Agave Salmiana, flowering at Intra, 176
 Agaves at Jean Verschaffel's, 533
 Ageratum at Castle Kennedy, 691
 Ageratum, new dwarf bedding, 466, 755
 Albumen of various seeds, the, 560
 Alders, notes on, 427
 Algerian wines, the importation of, 337
 Algeria, ravages committed by sparrows
 in, 113
 Allium unifolium, 366
 Alloplectus peltatus, 777
 Aloëcia Sedeni, 777; Thibautiana, 20
 Aloe chinensis, 231; A. chloroleuca, 38;
 A. platylepis, 38; A. tricolor, 503
 Alströméria pelegriana, 777

Amaryllis reticulata, on the culture of, 245
 Amateur gardening, 204, 332
 American Peaches, the early, 720
 American scientific surveys, 716
 America, extension of fruit culture in, 531
 Ampelopsis Veitchii, 267, 440, 468, 502
 Anatomy and functions of the leaves of
 Dionæa muscipula, 115
 Anatomy, comparative, and history of
 germs, 665
 Androsace sarmentosa, 529
 Anemiopsis Ludovici Salvadoris, 503
 Anemone fulgens, 198; A. japonica, 242,
 370; A. japonica alba, 534
 Annuals, hardy, grown at Chiswick, 152
 Annuals, in pots, 113; notes on new, 503
 Anona Cherimolia, 118
 Anthurium Andreanum, 231; trilobum,
 503
 Ants in meadows, 118
 Aphis vastator, 59
 Apogonot distachyon, 649, 692, 724,
 787
 Apple, the (Supplement, Sept. 15)
 Apple crop of 1877, the, 534
 Apple cultivation in Canada, 314
 Apple, Gravenstein, 787, 815; the "Ten
 Commandments," 469; Stone's, 745;
 Worcester Pearmain, 434, 532
 Apples for standards, 723
 Apples, on the culture of, 558
 Aquarium, the Potato Show at the, 468,
 500, 532, 564, 595
 Aquatic plants, on the culture of, 234
 Aquilegia californica hybrida, 503;
 coculea hybrida, 198
 Arads, on the culture of hardy, 524
 Aralia Sieboldi, 650, 726
 Araucaria excelsa, 777
 Arbutus andrachne, 813
 Arctic expedition, the, 715
 Arctic woodland, the, 58
 Ardisia Oliveri, 680
 Arthropodium neo-caledonicum, 503
 Artificial fruit, 187
 Artistic gardening, 531
 Arundo conspicua, 81; A. Donax, 500,
 565, 628, 660; flowering of, 597
 Arundo Doxax and the Pampus grass,
 534
 Ash of Celery, the, 598
 Ash trees, notes on old, 435
 Asparagus Dregeanus, 598
 Asters grown at Chiswick, notes on, 279
 Asters, notes on the best, 496
 Astilbe barbata, 525; A. rivularis, 500
 Attar of Roses, 275
 Auricula, alpine, Silvia, 231
 Auriculas at Kirky Malzeard, the, 302;
 the autumn culture of, 211; new, 434;
 notes on, 593; the old single white and
 lilac, 400
 Australia and California, a visit to the
 big trees of, 491
 Australia, Cinchonas in, 565; double
 flowers from, 726; the Pomegranate
 of, 562
 Australian Eucalyptus, the, 491
 Austrian Brier, the, 85
 Autumn foliage, 596
 Autumn flowering Iris, 373
 Autumn planting, 525, 342; Roses, 364,
 406
 Autumn, the Roseless, 270, 340, 374, 408
 Averrhoa Bilimbi, 626
 zæala imbricata, 198

B

BAGNOT Nursery, the, 488
 Bahamas, castor oil in the, 108
 Bahia, Tobacco culture in, 656
 Balsam on the culture of the, 178
 Balsamorhizon brevifolium, 108
 Bamboo, he, and its uses, 167
 Bangalore deciduous trees, &c., at, 119
 Banfishire, dimensions of trees in, 501
 Banksian Ææ, the single, 85
 Bannerman, fr. T. (with portrait), 52

Banyan Fig trees, notes on, 105
 Barnet and Highgate nurseries, the, 618
 Barometer, the, why it rises and falls, 58
 Barrota Pancheri, 777
 Battle of Life, the, 679
 Beadon, the Rev. Canon, the centenary
 of, 689
 Beans, on the growth of, 82
 Bedding-out, the, at Cleveland House,
 273, 592; at Doveridge Hall, 597; at
 Victoria Park, the, 212; in Queen's
 Square, Brighton, 262
 Bedding season, notes on the, 262
 Beds, summer, Pæonies for, 111
 Beech mast, the abundance of, 245
 Bees, do they massacre the drones, 142;
 enmity of queen, 402; introducing
 Italian queen, 462; Ligurian or Italian,
 247; queens, the number of in one hive,
 204
 Beet, the Egyptian Turnip-rooted, 306
 Beet, on the growth of, 563
 Begonia Davisii, 267; B. Empress of
 India, 248; B. metallica, 503; B.
 Monarch, 86; B. Moonlight, 530; B.
 Mrs. C. Scorer, 86; B. Queen of the
 Whites, 248; B. Royal Standard, 632;
 B. x weltoniensis, 85
 Begonia sports, 488
 Begonia tubers, how to winter, 439
 Begonias certificated at Chiswick, 152;
 hybrid, 86, 198; new seedling, 501;
 new tuberous-rooted of 1877, 456;
 illustration of some new, 752, 116, 439,
 501, 567; at Kew, 302
 Berlin, vegetable remains in the Egyptian
 museum, 563
 Bestwood, the conservatory at, 726
 Bignonia venusta, 786
 Birch, witch knots on the, 601, 759, 761
 Birds, shooting wild, 430, 462, 492
 Blackberries, white, 439, 468, 566
 Blackbird, a white, 216
 Blandfordia flammea var. princeps, 778
 Blandfordia, the medical gardens at, 243
 Bollen Lalindei, 632
 Bomarea oligantha, 648
 Bones, the value of charred, as manure,
 583, 660, 758

BOOKS:—Aveling's Physiological Tables
 for the use of Students, 568; Bailion's

 Farming, 299.

Border shaded by trees, plants for a, 694
 Borneo, origin of the Rajah Canes of, 51
 Boronia elatior, 237
 Boswellia Carteri, 690
 Botanic Congress at Paris in 1878, pro-
 gramme of the, 306
 Botanical Gardens, Adelaide, 136; Cam-
 bridge, Mass., 299; Hull, 601; Pisa,
 560; Melbourne, 529
 Botanist, the perils of a, 680
 Botany, fossil, 716; geographical, on the
 progress of, 529; of the Rocky Moun-
 tains, the, 552; village, 85
 Bottle for showing cut-flowers, 83
 Bougainvillea speciosa, 52
 Bowie, Mr. James, death of, 607
 Box Bower, Queen Mary's, 116
 Braemar, the Fir trees in, 504
 Branches, disarticulation of, 306
 Branches, trees rooting from the, 180
 Brassavola Digbyana, 86
 Brazil, the cotton industry in, 690
 Brier, the Austrian, 85; the copper-
 coloured, 17
 Britain, silk culture in, 439
 British Association, the, 214, 236, 266
 Broccoli, laying down, 629; on protecting
 winter, 619
 Broccoli, Gilbert's Selected Snow's, 787;
 the Leamington, 724; Veitch's autumn,
 690, 693, 726, 787
 Broomfield, the Phænotopsis-house at, 140
 Brownlows, on the culture of, 114
 Brngmansia suaveolens, the, at Castle
 Ashby, 368
 Budding, Rose (Supplement, July 7)
 Buddleia asiatica, 503
 Bud, influence of on the stock, 246
 Buffalo-horn manure, 244, 245, 721
 Bug, the Cattleyn, 244
 Bulbs, Dutch, 365; hardy, notes on,
 340; the depth to plant, 436
 Bulimus Goodallii, 726
 Burning clay, on, 437
 Burnley, the Edge-end Nursery, near, 212
 Butchers' Broom, 82; as a badge or crest,
 309; the uses of, 118, 180, 214
 Butterflies, golden, 429

C

CABBAGE, Carter's Heartwell, 17; the
 Santung, 248; pitchers on leaf of, 19;
 trial of, at Chiswick, 619
 Cactus, the Eagle's Claw, 180
 Caddice fly, the Rose, 119
 Cæsalpinia Buncdu, found on the coast
 of Cornwall, 504
 Calandrinia nitida, 146
 Calamus asperimus, 231
 Calanthes, notes on, 618; at Riddings
 House, 756; seedling, 593; Veitchii,
 756
 Calceolaria, shrubby, 754; C. Kayii, 565;
 C. lobata, 632

Calcot, recollections of, 393
 California and Australia, a visit to the big trees of, 491
 Californian Sequoia, the, 491
 California, the resources of, 650
 Callas or Richardias, 599
 Calliphurina Hartwegiana, 753
 Calochortus, varieties of, 118; *venustus* vars. *lilacinus* and *purpureus*, 70
 Camellia Madame Verschaffelt, 778
 Camellia Cocca, the, 726
 Camellias in Sussex, 277; culture of the, 297, 358
 Campanula macrostyla, 212, 275; *C. pyramidalis*, 243
 Canada, Apple cultivation in, 314; the forest trees of, 298, 364; notes from, 494; the Colorado beetle in, 246
 Candytuft, a new, 113
 Cane, the Rajah, botanical origin of the, 243
 Caoutchouc-yielding plants, on the culture of, in India, 146
 Cape or hood for hives, 401
 Caper Spurge, the, 19
 Capparis Mitchellii, 562
 Capsus Cattleysae, 244
 Carbon of plants, source of, 82, 181, 246
 Cardamoms, the winged, 594
 Card labels, waterproof, 659, 691, 756
 Carissa grandiflora, 198
 Carlisle, notes on gardens in the neighbourhood of, 210, 240, 275; the International Fruit Show at, 304
 Caroloduvica Drudei, 714, 753, 786
 Carnations and Picotees, notes on, 748; on layering, 300; on wintering, 627; Society, the, 17
 Carnation Souvenir de la Malmaison, 759; "Clove," Mrs. Matthews, 86; "Clove," Susan Askey, 302; tree, A. Alegatiere, 658; Osman Pacha, 441; winter-flowering tree, 658
 Carnarvonshire, a holiday in, 232
 Carnivorous plants, 277
 Carpet bedding at Doveridge Hall, 597
 Carpet bedding v. herbaceous plants, 629
 Carroll City, Iowa, notes from, 269
 Carya tomentosa, 245
 Caryota Alberti, 211
 Case for carrying and keeping eggs, 661
 Casimiroa edulis, fruiting at Kylemore Castle, 369, 400, 464, 496
 Castle Ashby, flower gardening at, 368
 Castle Coch, the vineyard at, 176; Castor-oil in Bahamas, 108
 Catasetum macroglossum, 552; *C. plasmia*, 488
 Cats eating Cucumbers, 211, 245
 Cattleya gigas, as a winter-flowering plant, 629; *C. picturata*, 584; *C. Wilsoniana*, 72
 Cattleya bug, the, 244
 Cauliflower, Autumn Giant, 726; Dean's Snowball, 629; the Eclipse, 724; Veitch's Autumn Giant, 724
 Caxton Exhibition, the, 18
 Ceanothus azureus, 275
 Celery, the ash of, 598
 Centropogon Lucyanus, 724
 Cephalotaxus Fortunei, monœcism in, 370
 Cephalotaxus, on the pitchers of the, 237
 Cerasus serratifolia rosea, 632
 Cerasus japonica, 243
 Cerif, Mdle, Henrietta, death of, 625
 Ceropegia Barklyi, 198
 Chamæcladon oblongifolium, 789
 Chærophyllum roseum, 778
 Charcoal for gunpowder, 140
 Cheiranthus Marshalli, 242
 Chery, a venerable wild, 504, 567
 Chery Currant, the, 180
 Chery, the May Duke, origin of the name of, 497
 Chervil, the Parsnip, 523, 566
 Cheshunt, the Roses at, 116
 Chestnut, Spanish, notes on some varieties of, 427
 Chimney cleaning, hints on, 633
 Chinese Primrose, the improvement in the, 689
 Chiswick, Cabbages at, 649; notes from, 133; Potatoes and Salus at, 39, 277
 Christmas, plants for decoration at, 743, 775
 Christmas Roses, 694, 724
 Chrysanthemums, a few good, 638; as decorative plants, 695; at Slough, the, 664; at Victoria Park, 659; in the Temple Gardens, 562; in villa gardens, 653; Japanese, 689; lateness of, 466, 562; new summer bedding, 497; notes on reflexed, 638; when to propagate, 779, 815; the best white, 786
 Chrysanthemum sports, some extraordinary, 754
 Cibotium pruriatum, 726
 Cinchona in Australia, 565
 Cinerarias and the frost, 627, 725, 758
 Cinerarias, on wintering, 466
 Circulation of the sap, on the, 104, 145
 Cissus antarctica, 659; *C. orientalis*, 302; *C. rhomboides*, 659
 Clay, burning, 437
 Clematis Jackmanni, 212; *C. Otto Freebel*, 212

Cleopatra's needle, 497
 Clerodendrons, on the culture of, 436
 Climate and flowers of England, 207
 Cliveden, the gardens and grounds of, 69
 Clover sickness, 82
 Coca, medical properties of, 400
 Coccus flocciferus, 726
 Cochineal culture in Teneriffe, 720
 Cockroaches in France, 337
 Cocoa culture in Surinam, 690
 Coelebogyne ilicifolia, on the reputed parthenogenesis of, 146
 Cologyne Mayeriana, 134; *C. Schilleriana*, 778
 Coffee as an antidote to strychnine, 529
 Coffee disease, 140
 Coffee, Liberian, 107, 168
 Colechicum autumnale, 429; *C. officinale*, 562; *C. speciosum*, 497; *C. speciosum rubrum*, 408
 Colechicums, notes on, 407
 Colias Edusa, 492
 Colletia cruciata, 497, 593; *C. cruciata* and *spinosa*, notes on, 617
 Colomia grandiflora, 466
 Colonial florists, 82
 Colorado beetle, the, 38, 112, 142, 150, 178, 214, 237, 324, 374, 656; in Canada, 246; La Doryphora in Belgique, 13, 16; Orders in Council relating to the, 210
 Colorado Spruces, Professor Sargent on the, 75
 Coloured leaves, 683, 724
 Coltsfoot, on the eradication of, 51
 Columbine, the feathery, 214
 Colwyn Bay, trees and shrubs at, 85
 Comfrey, the, 659
 Coniferæ, pruning, 526, 654, 749
 Conifer, slow growth and durability of, 4, 594
 Conservatory at Bestwood, the, 726
 Conservatories, designs for, 108
 Convolvulus arvensis, 370; *C. Scammonia*, 370
 Cooke, Dr. M. C., on the fungoid diseases of forest trees, 168
 Copings to walls, wood, 725
 Coprosma as substitutes for Coffee, 594
 Cordun training, 723
 Cornfields, novel way of clearing of insects, 371
 Cottage gardens, best fruits for (Supplement, Sept. 15)
 Cotton industry in Brazil, 690
 Cotton, the Bamia, in Egypt, 626
 Cottleodon Pestalozzeæ, 459; *C. stolonifera*, inverted growth of, 805
 Cyripedium patens, 456
 Cramp in fowls, 627
 Crane-fly, the, 444
 Crassula rubicunda, 562
 Crataegus Pyracantha, 434
 Creepers and plants on walls, 403
 Crinum brachynema, 778; *C. Moorei*, 302
 Crocus alatavicus, 198; *C. speciosus*, 429
 Crocus, the autumnal, 116, 562
 Crocuses, on planting, 407
 Crops, the season and the, 278
 Cross-fertilisation of plants, 306
 Cross, Mr. W. J., memoir and portrait of, 301
 Crotons, 661, 692

SALES BY AUCTION.

Oncidium Marshallianum. MR. J. C. STEVENS will SELL by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on TUESDAY, July 10, at half-past 12 o'clock precisely, an importation of fine plants of ONCIDIUM MARSHALLIANUM, just received in good condition from Brazil, &c. "Mondego."

Imported Orchids. MR. J. C. STEVENS will SELL by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on TUESDAY, July 10, at half-past 12 o'clock precisely, an importation of ODONTOGLOSSUM MADRENSE, O. CIRRHOSUM, O. PULCHELLUM, O. REICHENHEIMII, O. CITROSUM ROSEUM, and many other choice sorts; and a quantity of ESTABLISHED ORCHIDS, some specimen STOVE and GREENHOUSE PLANTS, &c.

Hammersmith Nurseries. GREAT CLEARANCE SALE OF NURSERY STOCK. MR. J. C. STEVENS begs to announce that he has received instructions to SELL by AUCTION, on the Premises, the Hammersmith Nurseries, W., the third and concluding portion of STOVE and GREENHOUSE PLANTS, together with the GREENHOUSES, PITS, BOILERS, &c., the land being required for building purposes.

Houghton Estate. ANNUAL TIMBER SALE.—Twelve miles from Lynn, ten from Fakenham, and seven from Snettisham Railway Stations.

WILLIAM C. HOPKING is favoured with instructions from the Most Noble the Marquis of Cholmondeley, to SELL by AUCTION, on WEDNESDAY, July 25, 200 splendid OAK TIMBERS, many of which are from 30 to 40 feet in length, of great girth and very clean. 130 ASH TIMBERS, and 14 ELM TIMBERS, some of which are 40 feet in length. A large quantity of OAK WRONGS, about 20,000 HARDWOOD FAGGOTS, and two large STACKS of BARK, the produce of the entire fell for this season of 282 Oak Timbers. The Bark is secured in very good order, and is of the best quality.

The Auctioneer has particular pleasure in calling the attention of Timber Merchants and the purchasers of Bark to the above-described Sale, it being the finest fell of timber offered for Public Competition on the Estate for many years.

Sale to commence at 10.30 punctually, in the Park, close by the road leading from Bircham to Rudham.

A Conveyance will leave the Globe Hotel, King's Lynn, and Fakenham Station at 8.30 o'clock for the convenience of Purchasers.

Catalogues may be had a fortnight previous to the Sale on application to W. FREUER, Esq., Estate Agent, West Rudham, Brandon; or to the Auctioneer, Great Bircham, Lynn, Norfolk.

TO BE DISPOSED OF, a SMALL NURSERY, containing about 3000 feet of Glass. Good Dwelling House. Apply to C. FAIRINGTON, 16, Maida Vale, Edgware Road, N.W.

TO BE LET, at £18 per annum, 2 ACRES of LAND, with little Meadow and Streamlet, a small Four-roomed House, Wash-house, Outbuildings, &c., for Farm or Nursery. Healthy village—5 miles from station. Smaller one, £8 per annum. Freeholds easy terms. H. FLETCHER, Wellow, Romsey, Hampshire.

TO LET, a FARM of 52 ACRES, great title free, partly drained. Three-quarters of a mile north of Crawley Station, well situated, and fronting on the main road from London to Brighton, in Ifield Parish, Sussex, called Martyr's Farm. Well adapted for a London Milk Business, one-fourth of it being excellent Meadow, and more could be laid down. Old-fashioned House, capital Barn, Stables and the usual Out-buildings. Good liberal terms from Michaelmas next, and easy covenants to an enterprising tenant. To be viewed by permission of the present occupier, Mrs. LILL WHITE, and full particulars of Mr. A. WELLS, Stoke Hill Farm, Guildford.

Joseph Smith, deceased. Pursuant to the Act of Parliament of the 23d and 23d Vic., cap. 35, intitled "An Act to Further Amend the Law of Property, and to Relieve Trustees,"

NOTICE IS HEREBY GIVEN, that all Creditors and other Persons having any CLAIMS or DEMANDS upon or against the Estate of JOSEPH SMITH, late of Tansley, near Matlock, in the county of Derby, Nurseryman, deceased, who died on the 1st day of June, 1876, and whose Will was proved on the 11th day of July, 1876, in the District Registry at Derby attached to the Probate Division of Her Majesty's High Court of Justice, by Samuel Smith and James Smith, both of Tansley aforesaid, Nurserymen, the Executors named in the said Will, are hereby required to send particulars of their CLAIMS or DEMANDS to the said EXECUTORS on or before the 1st day of AUGUST next; and Notice is hereby also given that after that day the said Executors will proceed to distribute the assets of the said Joseph Smith, deceased, among the parties entitled thereto, having regard only to the claims of which the said Executors shall then have had notice, and that they will not be liable for the assets, or any part thereof, so distributed to any person of whose claim or demand they shall not then have had notice—Dated this 10th day of June, 1877.

ARTHUR HARWARD, Wickswoth, Solicitor to the said Executors.

SUTTON'S

IMPROVED STRAIN
OF

CALCEOLARIA

"PERFECTION."

After many years' careful selection we have succeeded in producing a strain of Calceolaria which, for beauty and form of flower, richness of colour and habit of plant, is acknowledged to be one of the finest in cultivation. Our houses have been visited during the blooming season by some of the most eminent authorities of the day, all of whom agree in pronouncing our Improved Strain to be of unusual excellence.

Price, 3s. 6d. per Packet, post-free.

From "THE GARDEN," June 2, 1877.

"The Calceolarias at Messrs. Sutton & Sons' Nurseries, Reading, are just now beautifully in bloom, and should be seen by all who take an interest in this class of plant. The strain is one of the finest, being the result of years of careful selection. Many of the individual flowers measure 2½ inches across, and are perfect in shape and colour."

From "THE GARDENERS' CHRONICLE," June 2, 1877.

"A remarkable collection of Calceolarias is now in bloom at Messrs. Sutton & Sons' Nursery, Reading. The house, which is of good size, is ever crowded with specimen plants, but it serves to show off their great beauty and attractiveness en masse. Each plant is densely laden with large flowers, and the colours are very varied, from creamy white handsomely spotted on the body to rich dark maroon."

From MR. B. BARHAM, Gr. to the Right Hon. the Earl of Sefton.

"It affords me great pleasure to be able to inform you that your Calceolaria seed has given extreme satisfaction. I have just now in flower one of the finest lots of hybrid Calceolarias I have ever seen my lot to look upon. They are excellent in variety, form, and size of flower. Many have seen them and are highly gratified."

From "THE GARDENERS' MAGAZINE," June 2, 1877.

"The strain of Calceolarias distributed by Messrs. Sutton has flower-heads of immense size and perfect in contour. The flowers, which are borne in huge clusters, are of immense size and of the finest possible shape, and embrace every colour. The yellow ground flowers are as a matter of course the most strongly represented, and with their splendid crimson markings are wonderfully effective, and of those of a straw-coloured ground and spotted and marked with purple, these are sufficient to make a most pleasing variety. The rose and purple self-flowers, some of which are quite new in colour, are also numerous, and present a striking contrast to those spotted with crimson, purple, and rose respectively. Sutton's strain of Calceolarias may certainly be said to combine all the good qualities yet found in these attractive flowers."

From A. E. RUSSELL, Esq., Dalnabreck.

"My Calceolaria plants from seed purchased of you last year are particularly fine, of very compact habit, and beautiful in colour."

From MR. W. GEARLE, Gr. to R. M. Jaques, Esq., Easby Abbey.

"I have some very fine Calceolarias from seed supplied by you; they are the admiration of all who see them."

W. H. LASCELLES, 121, BUNHILL ROW, FINSBURY, LONDON, E.C.

J. J. THOMAS & CO.'S GARDEN REQUISITES.

NEW ELASTIC GARDEN CHAIR, With WOOD SEAT and BACK, and WROUGHT-IRON FRAME. No. 350.

This article is generally admired, and a great favourite with the ladies; being ornamental, combined with strength, elasticity, and lightness. For export it can be packed close. If preferred, it can be made entirely of wrought iron.

	Each.	s.	d.
Iron-work and wood, painted dark green	7	6	
Iron-work, japanned green, wood stained and varnished	8	0	
Japanned green with lines	10	6	
Real oak, varnished	11	0	

With Arms, 4s. extra.

THOMAS'S EXTRA STRONG CROQUET TENTS.

Length.	Width.	Height of Eaves.	Height of Ridge.	£	s.	d.	Packing Case.
10 feet	8 feet	5 feet 6 inches	8 feet 6 inches	6	10	0	7s. 6d.
12 "	8 "	6 "	9 "	8	10	0	8s. 6d.
15 "	10 "	6 "	10 "	13	10	0	10s. 6d.

The framework is made of light iron tube, so fitted that it can be taken to pieces in a few minutes. The usual upright supports and outside lines are entirely done away with, the interior space being quite clear of all obstruction. The blue and white striped awning and curtain give these tents a very pretty appearance.

INDEPENDENT AWNING OR TENT, TO FIX IN GROUND. No. 384.

Suitable for using with any Pattern Garden Seats or Tables. Has wrought-iron Ornamental Frame, fitted with pronged feet, to fix in ground; so simple in construction that any one may fix it in a few minutes. The winding apparatus very simple and effective, the cloth can be instantly rolled up or lowered at pleasure. Extreme width within, 6 feet 6 inches.

Price, with best striped waterproof cloth, wove specially £3 0 0
Zinc cover, extra 0 10 0
Storage box, extra 0 5 0

THE CROQUET GARDEN SEAT. No. 366.

Under 6 feet, with two supports; 6 feet and above, with three.
This seat combines elasticity, comfort, strength, and durability, with an elegant appearance, and is easily taken apart when required.
The wrought-iron supports are painted green. A key for screwing up the bolts and nuts is sent with each Seat. The woodwork, stained and varnished, is, for convenience of carriage, packed in bundles, and the iron supports are tied together. (See Illustration annexed.)
These Seats are strongly recommended for Terraces, Promenades, Lawns, &c., and are suitable for all climates and situations.

SALUS

Crack Nature's Moulds, all Gormens spill at once.
KING LEAR, Act iii., Se. 2.

No Mildew, Blight, Fungus, or small noxious Insect or Worm can withstand the application of SALUS.

SALUS destroys the Mildew of PEAS.
SALUS destroys the Mildew of HOPS.
SALUS destroys the Mildew of ONIONS.
SALUS destroys the Mildew of ROSES.
SALUS destroys the Mildew of LETTUCES.
SALUS destroys the Black Moulds of APPLES and PEARS.

SALUS destroys the Mildew of POTATOS.
SALUS destroys the Mildew of the VINE.
SALUS destroys the Mildew of CABBAGES.
SALUS destroys the Mildew of PARSNIPS.
SALUS destroys the Mildew of SPINACH.
SALUS prevents the CUCUMBER DISEASE.
SALUS prevents the MELON DISEASE.
SALUS prevents the HOLLYHOCK DISEASE.
SALUS destroys all minute parasitic worms and small noxious insects.

SALUS has an extraordinary effect in preventing disease, and promoting extraordinary growth in CARROTS.

See *Gardeners' Chronicle*: for June 2, 1877, p. 696: letter from Mr. Fish, *Gardeners' Chronicle*, June 23, 1877, p. 792; *Gardeners' Chronicle*, June 30, 1877, pp. 818 and 821.

If SALUS is mixed with water for applying to the roots of plants, or for use through the syringe, a 14 lb. box of SALUS is sufficient for 100 gallons of water.

A SALUS DISTRIBUTOR will be enclosed if required, at an additional charge of 6d.

Mode of Distributing SALUS in the Fields by means of the SALUS DISTRIBUTOR.

SALUS is a dry impalpable powder, of such extreme lightness that the slightest possible agitation of the SALUS DISTRIBUTOR disseminates the SALUS in almost invisible clouds through the air. SALUS should be distributed broadcast in the morning, or at mid-day. The moist air of evening will dissolve SALUS, and every individual grain will prove FATAL to ALL SMALL FUNGI and MINUTE PARASITES. Any rustic lad can distribute SALUS.

The cost of 14 lb. box of SALUS is 1s.; the cost of 7 lb. box of SALUS is 7s., free to all London Railway Stations. Orders amounting to £5 and upwards free to all Scottish Railway Stations and Irish Ports.

A Sample Pack 1, with instructions, will be forwarded, post-free, on receipt of 1s. 4d.

STAND No. 428.

No. 75.—MELON FRAMES AND FORCING FRAMES.

The Largest Stock in the Kingdom. Ready to be despatched on receipt of Order.

These Frames are made the best red deal, thoroughly seasoned, and fitted by first-class workmen, 24 inches high at the back, 13 inches high in front; painted three coats of good oil-colour, glazed with best 21-oz. glass, every pane of which is nailed in and bedded in putty, the best method of glazing known, and adopted by the most eminent builders and leading nurserymen (see *The Garden* for January 13, 1877, page 30). Iron handles to each light, and an iron strengthening-bar across. Each light is 6 feet by 4 feet, and 2 inches thick.

CASH PRICES—CARRIAGE PAID.

Special Notice.—Carriage paid to any Railway Station in England. Also to Dublin, Glasgow, and Edinburgh on Orders of 40s. and upwards.

Breakage seldom occurs. Should any glass be broken, we will send sufficient to replace carriage free.

No. 74.—NEW THREE-QUARTER SPAN-ROOF GARDEN FRAME.

Our illustration shows a New Frame for growing Cucumbers, Melons, &c., and for storing plants. It is made to give greater height and more convenience than the Melon frame, No. 75. The front is 11 in. high, without the light, 32 in. high at the ridge, and 22 in. high at the back. The front lights can be turned back on the lights behind, and back lights turned on to the front lights, giving access to all the plants inside. They are made of the best red deal, sides and ends 1 1/4 in. thick, 2 in. lights; all are painted four times, and glazed with 21-oz. sheet glass, nailed and putted in, same as the Melon Frame, No. 75. The illustration shows the lights to open with gearing; any of the lights can be lifted up when required without altering the other lights. Back and front gearing work separately.

CASH PRICES—CARRIAGE PAID.

Carriage paid to any Railway Station in England, also to Dublin, Edinburgh, and Glasgow.

Packing Cases are charged, and half of the cost allowed if they are returned in good order, carriage paid, to our Works, within a month of delivery of the frame.

NOTICE.—A New Catalogue, richly Illustrated with Designs of Horticultural Buildings to suit every purpose. This Book will prove itself of real service to all persons intending to erect such Buildings. Post-free for 24 penny stamps.

SEEDS OF PRIZE FLOWERS.

CATALOGUE of SEEDS,

With every Article Priced, on application.

[ALL HALF NATURAL SIZE.]

Mr. William Bull's
PRIZE STRAINS OF
PRIMULA SINENSIS.

PRIMULA SINENSIS FIMBRIATA.

Seed of Mr. WILLIAM BULL'S select and unrivalled strain of this useful and favourite plant is now offered in mixture containing all the new and most distinct colours and varieties. The many unsolicited testimonials received at Mr. Bull's Establishment point conclusively to the fact of its being appreciated among growers as an unequalled strain. To distinguish this from the ordinary mixture of P. alba and rubra usually supplied, Mr. W. B. designates this choice mixture as

"BULL'S PREMIER MIXTURE"

1s. 6d. and 2s. 6d. per Packet.

From Mr. T. GODFREY, Gardener to Lady Jolliffe, Southwood House, St. Lawrence.

"From the Primula seed I had from you I have such a variety of colour I never saw before—white, violet, pink, a beautiful rose, lilac, and a brick-red; without exception I never saw their equal."

From Mr. WYNN, Gardener to J. R. Lowe, Esq., Wothorpe, Stamford.

"The strain of Primula seed I had from you last spring have turned out to be extremely fine, many of the single flowers being about the size of a crown piece, the colours being exceedingly rich."

From Mr. R. EVANS, The Hall Gardens, Bushey.

"Your Primulas were all that one could wish for—fine flowers and robust growers; some of the plants were nearly 2 ft. through."

PRIMULA SINENSIS FIM. ALBA,
PRIMULA SINENSIS FIM. RUBRA,

Extra Choice, 1s. 6d. and 2s. 6d. per Packet.

From Mr. E. ABBOTT, Nurseryman, Ardleigh, Essex.

"Your Primulas I am blooming now are a splendid strain. I hope you will send me some again."

From Mr. E. COOLING, Nurseryman, &c., Derby.

"Your Primulas were first-rate here this season."

PRIMULA S. F. FILICIFOLIA ALBA,
PRIMULA S. F. FILICIFOLIA RUBRA,

Extra Choice, 1s. 6d. and 2s. 6d. per Packet.

From Mr. C. SMITH, Gardener to Sir A. E. Guineess, Bt., Clonsarf, Dublin.

"I was much pleased with all the Primula seed I got from you: they are truly superb. The filicifolia alba and rubra are most remarkable; the foliage is exquisite, with flowers so well thrown up above."

NEPHRODIUM TRUNCATUM,
PANAX LACINIATUM,
SADLERIA CYATHEOIDES,
SMILAX SHUTTLEWORTHII.

NEW REGAL PELARGONIUM,
PRINCE OF WALES.

This is an exceedingly handsome variety of this new and popular class of Pelargoniums. It is of excellent habit, very free blooming, and produces good trusses of large effective flowers; they are not really double, but from their fullness of form and extra number of petals, which are prettily undulated, they have the appearance of being so. The colour is a bright vermilion with light centre and light edge to the petals, the superior ones being marked with light crimson and darkly blotched. It is much brighter in colour, larger in truss, and very superior in every way to Pelargonium "Captain Raikes."

Price 1 guinea each.

COLEUS PICTUS.

This distinct and attractive plant has been introduced from Duke of York Island. Its divers colours are curiously blended and very effective, the leaves, which have a green ground, being more or less but variably flushed with yellow in irregular patches; the leaves are also marked in the direction of the veins with longitudinal bars, varying in size and outline, of a rich chocolate brown, which, where it meets the parts flushed with yellow, assumes a reddish-brown hue. The marginal teeth are bordered with chocolate colour. These peculiar markings, and the unusual form of the leaves, give the plant a bizarre and curious appearance.

Price 10s. 6d. each.

Mr. WILLIAM BULL'S ILLUSTRATED CATALOGUE for 1877

Contains Names, Descriptions, and Prices of the above and various other New Plants, and can be had on application. Price 1s.

CINERARIA, Weatherill's Extra Choice Strain, 5s., 3s. 6d., 2s. 6d., and 1 6

From Mr. J. WEST, *Gardener, Chaddon Park*, May 21, 1877.
"Sir,—Your strain of Cinerarias, which have now been in bloom some time, have been and are now the admiration of all that have seen them, and are considered by gardeners to be the best ever seen in this neighbourhood. Habit very dwarf and compact, quite equal to the drawing in your catalogue."

CYCLAMEN PERSICUM GIGANTEUM (new) 2s. 6d. and 5 0
Do., do., do., Williams' Superb Strain, 5s., 3s. 6d., 2s. 6d., and 1 6

VICTORIA and PARADISE NURSERIES,

SATURDAY, JULY 7, 1877.

ROSES FROM NEW LIGHTS.

OLD plants in new positions often possess all the charms of novelty. The standpoint, the light, the angle of vision, make all the difference. The Rose, for instance, prone on the wet ground, after a dashing rain—top-heavy, moist, splashed, soiled, water-logged—is different and almost as the poles asunder from the same Rose in bud, gemmed with pearls in the cool sweet stillness of a June morning or evening. Again there are wider differences of degrees of beauty and enjoyability between dwarf Roses and standards, Roses in bushes and the self-same Roses or others running over an arch, climbing up a tree, or wreathing a dead ruin, bound with three-stranded cords of life, verdure, and colour. And so potent is the power of circumstance in the appraisal and enjoyment of the beautiful—that the oldest Roses become, as it were, new, when seen in new lights, such, for example, as running up and round a chimney, forming a wall covering of matchless grace and beauty, clothing the roofs of dwelling-houses or outbuildings, rendering healthy and sweet the streets of crowded towns with their matchless freshness and fragrance, and furnishing architectural walls with richly embroidered panels and pillars of living colours, loveliest forms and perfumes—at once healthful, pleasant, and antimalarious—such are a few of the new lights in which Roses might be placed, to the obvious advantage of the Rose and ourselves. For, be it frankly acknowledged, the most gloriously beautiful and richly fragrant of all our flowers, the Rose, suffers much from our intensely conservative modes of treating. As a rule, it is forced into a dwarf or standard of three lights—dwarf, half tall, or, if allowed to run, it must run by iron or wooden lines, and keep to them with mathematical precision. The result is a dreary monotony of Rose form, which is foreign to its nature.

Others, again, look upon the Rose as made for showing. By all sorts of clever devices the flowers are forced into perfect form, huge size, solidity, substance; they are displayed in boxes like soldiers at drill, and the end is another trophy or silver cup to the sideboard, or a few more guineas in the exhibitor's purse. This is all very well, and has proved most useful in its way, but the time of launching a new society for the special fostering of the Rose seems opportune for advocating a wider sphere, a nobler freedom—larger liberties for Flora's queen, and the placing her in such open lights as those here indicated.

It may seem at first sight a digression to propose to send our Roses up chimneys, but a moment's consideration will prove the contrary; for is it not the highest mission of beauty and goodness to convert the unbeautiful into comeliness, the bad into good? Now chimneys are horticultural and artistic nuisances in more senses than one. They disfigure and defile the loveliest landscapes. Tall shafts shoot up into the sky, bold and bare in their mockery of the graceful lines of the trees which the one-shaft system obtains, and whole battalions of black stumps rising above crystal roofs, where every house has its chimney, suggesting the idea of a host of black dwarfs, each with huge short pipes

vomiting forth clouds of soot and smut. Chimneys are the terrors and stumbling blocks alike of landscape gardeners and architects. No art can raise them into things of beauty, no genius bend them into harmony with the flowering hues of living landscapes. But where art and genius fail, the Rose, which is more, better, higher than both, succeeds. Let such a Rose as the climbing *Devoniensis*, for example, enfold the ugliest chimney in the country in the rich drapery of its noble shoots, lovely ample foliage, and pure sweet flowers, and the chimney is transformed into a thing of matchless beauty—a joy for ever, the delight of all beholders, the eye, the glory, the delight of the garden. This is no romance, but the fact. While I write, a square bright chimney of the plainest type is before me. It is wide and tall, and the top crowned with a white pot. All is nearly hidden, and the very pot entwined with this splendid Rose. From base to summit the chimney is clothed with verdure, and showers down sweetness from a perfect crowd of noble fragrant Roses; the chimney has, in fact, become a noble polished shaft of beauty—a pillar of sweets. Therefore, to any one who may be trying, and trying in vain, to bring stiff, formal, unpracticable chimneys into harmony with the soft, flowing beauties of landscape art, the advice may confidently be given to try Roses. There are many Roses, such as *Gloire de Dijon*, and other strong growers, that will answer equally well, but none better for chimney adornment than the climbing *Devoniensis*.

Next to chimneys, perhaps, the even monotonous equality of light sky-hue of wall copings are the most determined and persistent artistic blots in and about gardens. Walls are necessities in gardens, though they are often multiplied with a recklessness that would point to the bricklayer and builder having combined with his useful qualities of a mason or a bricklayer also that of garden artist. It is difficult to account for the redundancy of walls about many demesnes on any other hypothesis. But our business now is, not with their origin, but their improvement by means of Rose copings. The artistic weakness of copings rests on their evenness. It is impossible to make an even skyline artistic. The attempt has often been made by the use of belts or screens of shrubs and trees. These, too, have often been planted so near as to exhaust the ground by their roots, and so monotonous as to be almost as formal as the walls themselves. Rose copings deal directly with and break up the level tops and smooth surface of walls; for nothing can be easier than to allow Rose shoots to grow to unequal heights on the tops of walls—now rising like the crest of a wave, and anon a long shoot running up like a dash of spray, and again all falling on the wall-top like descending into the trough of the sea. The artistic planter or trainer will also allow a few shoots or sprays to wander or fall over the face of the wall at times, as if by accident—just as a lonely ringlet will steal out from under Mary's sober cap in spite of her mistress's order and against her maid's will! Thus living copies of grace and beauty dissolve, as it were, into the hard-and-fast line of the walls, and cause them to melt readily into the surrounding landscape. The Roses link the dead bricks and stones on to the living shrubs and trees, and the walls, no longer a blot, become a substantial part of the beauty and richness of the finished picture. Some of the stronger and common Roses, such as *Ayrshire*, *Boursault*, *Noisette*, might be used to form the basis of the living coping; and other and choicer Roses could be worked on to these for forming sprays and furnishing greater diversity of colour and form.

Roses in the streets of towns may seem to be placed in a position in which the light would be too glaring and the dangers too many and too great for their safety; but the result would

prove so charming that it is worth an effort to accomplish it. Two revolutions are needed before roadside or street houses generally can be garlanded or furnished with the beauty and sweetness of the Rose; one has regard to taste, the other to petty morality. The thing is physically practicable on most roadside houses. In the majority of provincial towns, culture and scavenging could master the physical details. An intense desire for street Roses would bring them into the streets, and also force them to grow and thrive there. Then, to insure the safety of the Rose, there must also be a revolution in our national views of petty morality. The time may come when an unprotected Rose will be as safe in Piccadilly as an unprotected woman is now in a railway carriage or public park.

Roses on the housetops would be in safer quarters and in better light than in the streets. Here are miles on miles square to be conquered and won to the empire of Beauty, now given up to sheer deformity, burglars, and smuts. Each Rose on the housetop is a direct contribution to the purity, beauty, sweetness, and enrichment of the country and the world. No doubt many dwelling-houses are almost too high to be thus crowned with glory and honour. But Roses may be grown in pots and tubs on the leads. And then what a dreary waste of low roofs are presented by kitchens, outhouses, stables, warehouses, workshops, sheds, piggeries, &c. It is an easy matter to plant stray Roses to climb the walls and overspread the roofs of all such dwarf buildings of low stature. What at once so beautiful and so sanitary as wreaths of Roses drooping over stables, cow-houses, piggeries, kitchens, wash-houses, workshops, and other buildings. The overlooking of low roofs from upstairs sitting and drawing-rooms mars the pleasure of most houses more or less. Clothe the lower roofs with Roses, and their deformity is hidden and, more, the roofs themselves are thereby converted into the richest and most delightful part of the whole garden. Spring-growing Roses also revel in the freedom the roofs afford. Freed from the fetters of the precise trainer, the Roses ramble at their own sweet wills, with forms and styles of beauty unknown and undreamed of by Roses even in any other light than the clear, stimulating, bracing light and air of the housetops.

Roses in panels and on pillars of walls would also present them in charming and novel lights. The whole of a short wall might be furnished with Roses of sharply contrasting colours—such, for example, as panels of *Princess Camille de Rohan* or *Duke of Edinburgh*, separated with pillars of *Devoniensis*, *Boule de Neige*, or *Baroness Rothschild*, or *vice versa*. Then again, on long walls, each panel and each pillar or projection could be furnished with a separate Rose of a distinct colour; each beauty would then be presented in sufficient mass to fill the eye at once, and in bulk enough to reveal and display its natural habit and style. Golden beauties could be contrasted with scarlet, reds and pinks with whites, &c., thus adding to the beauty of each Rose by sharply-defined contrasts and pleasing harmonies. When sharper contrasts might be desired, the pillars might be formed of *Ivy*, *Clematises*, or *Golden Honey-suckle*, and the panels be filled in with *Roses*. The wall copings might also be of other and contrasting *Roses*, *Virginian Creepers*, or other climbers; but the two families—those of *Roses* and *Clematises*—are strong and rich enough to make one of the most rich and lovely walls in the world between the planted or the panel style. Walls thus richly embroidered or inlaid with beauty would prove among the grandest features of the garden, while the *Roses* thus exhibited in new and better lights would show to much higher advantage and, far more telling force than the higgledy-piggledy mixtures of weedy-looking *Roses* that one too often meets with on even the best-managed *Rose walls*.
D. T. Fish.

SEASONABLE ROSES.

THE uneven English climate, with its seasons never twice alike, renders a larger choice of *Roses* necessary than we should otherwise include in our lists. For example, this present season, with its glorious heat, making all *Roses* alike grow splendidly, has put *Aors de combat* at the exhibitions *Duke of Edinburgh*, *The General*, *Bessie Johnson*, *Dupuy Jamin*, and *Mdme. Victor Verdier*—the leading flowers of last year's shows. But who would think of discarding them or other thin but finely-shaped *Roses*, on the average so very good? Contrariwise, the very durable *Roses*, such as *Edward Morren*, *Beauty of Waltham*, *Marie Rady*—how gloriously they have opened their last year but seldom seen blossoms.

Then what glory of colour has there not been in the rose-coloured *Roses*, *Monsieur Noman*, *Annie* and *Emily Laxton*, *Marguerite de St. Armand*, *John Hopper*, and *Fraoçois Michelon*? They have come with a clearness of colour to the very edge of the petals, and so soft and tender in tint, as to remind us that after all rose-colour is the natural (the one Nature chose) hue of our flower.

Can one look on a perfect bloom of *Henri Ledechaux* (a souvenir of a good honest rosarian, now no more) and not believe in Nature's certain choice?

Yet to come are the lighter-coloured *Roses*, *Baroness Rothschild*, *La France*, and *the Teas*, and all the fine reds, which we hope to see, ere this is printed, rich in all their glory at the National.

New Roses of the Past, Present, and to Come, 1875-1876.—These are just blooming for the first time here in condition to judge if they are to be seasonable *Roses* in England. With rare faith we buy all that are described as extra superb, and count ourselves happy if year by year six or eight suit, or are pleased with our conditions and climate. The *Rose grower's* conditions here are stringent—perfect shape, perfectly bright colour, good size, and distinctness from all existing kinds, and forty to sixty such to arrive every year! There are happily in other lands those who like, for instance, *Triomphe de l'Exposition de France*, and other *Triumphs* of large rough *Roses*. Fancy a horticultural society giving a gold medal for the raising of *Paul Néron*—which ought to have inscribed on it "large and ugly." So the season 1875-76 has yielded its average, and they are, in the opinion of the writer, *Duchesse de Vallambrosa*, a light *Jules Margottin*; *Abel Carrière*, a bold dark *Jean Liabaud*, from the gardens of its worthy originator and namesake amongst the silk-ooms of the *Croix-Rousse*, at *Lyons*; *Jean Soupert*, hardly double enough; and *Madame Prosper Langier*, a new, bright, pure *Rose*, of more than the growth and vigour of *John Hopper*; *Marguerite Brassac*, a brighter *Charles Lefebvre*; *Avocat Duvalvier*, a grand *Andry-like* flower; and the good early *Rose*, *Arthur de Sansal*. We English growers (to proceed to praise ourselves) have no need to blush when against the above we match our contingent for the year in *Letty Coles*, *Mrs. Baker*, *Oxonian*, *Duke of Connaught*, and *Sultan of Zanzibar*.

The Roses for 1876-77.—A run round the French gardens has not improved the opinion formed here of them. *Marquis de Nivernais*, almost white, and *Madame de Montchauveau*, very light, are both good, the latter perhaps the best; *Madame Sophie Tropot* and *Marie Louise Pernet* are both globular roses of merit. *Monsieur Fihon* has a deal to beat in *Henri Ledechaux*.

The *Roses* of the future, what are they to be?—a yellow hybrid perpetual *Jules Margottin*, with intermediate shades of orange; pure scarlet *Duke of Edinburgh*, to which the present writer hopes to contribute some little help—hardy white *Teas*, both of the *Gloire de Dijon* race (ought these not to be a class by themselves called, say, *Dijon Roses*?) and of moderate free-blooming habits; climbing red and white *Roses* with the vigour of *Félicité perpétuelle*, the most glorious arch *Rose*, the November flowering habit of the old common *China*. The above is but a prophecy, but already, as one has seen, on the way to its accomplishment.

Rose Judges.—The introduction of the ballot in the choice of the judges at the National seems a move in the right direction: may not some of the shows adopt it with advantage? Need I express what has been the re-echoed opinion of growers for many years—that *Rose judges* should have exhibited *Roses* successfully themselves?—to add, must have grown them

successfully, is needless: from good plants only come good flowers.

Success to the National!—which I hope in every way your report will second—seems almost assured. The late fixture, to suit the Manetti growers, seems to have brought it just to the right moment, and overflowing coffers from the expected thronged attendance will let the Society do its other work well and easily. *George Paul, Cheshunt.*

MARCGRAVIA PARADOXA.

MANY of the visitors to the last great show of the Royal Horticultural Society were not a little puzzled at the appearance of flat green leaves growing on a board without soil or other food beyond that derived from the air or from the water with which they were moistened. In general appearance the plant is not unlike Ivy, especially the variety *Regneriana*, and Ivy like it emits a number of aerial roots, by which it clings to the board or other support. When the stems are in any way detached from the wall or rock upon which the plant grows naturally (in tropical America), the shape of the leaves becomes materially altered. But the most extraordinary feature presents itself when the plant flowers. The flowers are placed in umbels, each flower-stalk starting from the axil of a tubular bract or pitcher, which gives the flower a very singular appearance. The plant from which our illustration was taken (fig. 2) was exhibited by Mr. William Bull. Mr. Worthington Smith, who has examined the leaves microscopically, remarks that the under-surfaces of these leaves, although closely adpressed to the wood, have the usual number of stomata, interspersed with very peculiar hairs, like minute long-legged insects, as shown in the illustration (fig. 1).

A ROSE GARDEN.

I HAVE for many years seen Roses blooming by the acre, brilliant and beautiful, but although the blooms singly are all that can be desired for colour and size a field of Roses does not entirely realise the conceptions that arise in the mind after witnessing the devoted homage given to the Rose by all poets from Hafiz and Ferdousi to Swinburne. The last-named poet is as lavish in his praise of white Roses and red as any Persian poet. Not being able to read Hafiz or Ferdousi in their own language it is not easy to realise their poetry, but the worship of the Rose by them is unmistakable, and the source of their verses seems in a great part to be the Rose. In England we cannot connect the nightingale with the Rose, as he will not siog in our climate when the Rose blooms: it is perhaps different in Persia. I am, how

beauty of the landscape in any greater degree than so many Gooseberry bushes, but the cultivation there must have been extensive in his time, one European speculator having, it was said, 30,000 acres for the manufacture of attar. St. Joho's travels were published in 1845, and it is a little singular that none of the many recent travellers in Egypt have ever alluded to these Rose gardens, but from the sameness of the

a romantic shadow to the garden in the evening and shade from the sun at noonday, a greensward with a stream passing through it and alcoves of Roses yellow, white, and red, tall trees festooned with Roses, trees of Roses, bushes of Roses, pyramids of Roses rising from the ground to the height of a neighbouring fountain playing to 20 or 30 feet. Water must be cunningly dispersed that each thirsty Rose may drink—and Roses are thirsty—hedges of wild Roses for furtive walks offering an escape from the oppression of too much artistic beauty, and the bright moonlight of the Touraine to bring out the late beauties of the garden to be enjoyed without the fear of damp so everlastingly present in this provokingly cool climate. In my ideal climate and garden I should place such Roses as Hafiz never dreamed of—*Solfaterre* growing unfettered in all its wealth of dreamlike beauty, which, when once seen, is to be remembered. A cluster of this Rose which I once, and only once, saw in perfection has been an ever-present picture. *Devonensis* in thick hedges, *Maréchal Niel* as a pillar of gold—scores of names arise difficult of decision as to merit, the aristocracy, as usual, leading—*Duchesse de Vallambrosa*, *Marchioness of Exeter*, *Marquise de Castellane*, all worthy of their rank, and the brilliant, not by rank at least by merit, *Xavier Olibo*, *Charles Lefebvre*, and their compeers. Names are, however, bewildering, and the Rose garden must be enjoyed without such an arduous study.

As the Rose garden to be complete must be peopled by humanity, my Rose garden must be presided over by the amiable rosarian, M. Alphonse Karr, attended by his wasps, no longer venomous, but tamed by his example, and as a companion poet and rosarian, Mr. Algernon Swinburne. From verses on Roses, he will surely pardon me if I claim him as a Rose fancier; and the ladies—ah! these gentlemen must choose their own ladies.

Will the procession of the equinox ever permit us to have a Rose garden in England worthy of the name? *T. F. Rivers, Sarubridgeworth.*

THE COLORADO BEETLE.

THE following is a free translation of a passage from the clever squib, *La Doryphora en Belgique* (Liège, 1877), that was read by Mr. Andrew Murray in his lecturette on the Colorado beetle at the general meeting of the Royal Horticultural Society on Tuesday last:—

"I must first tell you what took place last night at the Ministry of the Interior at Brussels. It is a necessary introduction to the comprehension of the truthful recital I am about to make. Let us transport ourselves then to Brussels—to the Ministry for the Interior, in the private cabinet of the Minister.

"It must have been about 9 o'clock at night, or nearly so. The Ministers entered one after another, and took their places silently round the table where their colleague was already installed. Besides him there are four—M. Malou, Minister of Finance, Chief of the Cabinet M. d'Aspremont, Minister for Foreign Affairs;

FIG. 1.—MARCGRAVIA PARADOXA.

Showing cells and stomata from under adpressed surface of leaf, and peculiar irregular hairs.

colour there can be little poetry in the prospect. My own recollections of the Rose gardens of France, another classical Rose division of our planet, are generally associated with a hot ride in a rickety third-class carriage, a tramp over fields knee-deep in dust, an interview with a sunburnt genial and enthusiastic cultivator, whose energies are devoted to pointing out the beauties of a seedling or seedlings which he is anxious to introduce to the English Rose speculator, receiving in return a substantial share of the wealth supposed to exist everywhere in England—the Roses being intermixed with crops of Wheat, Hemp, Poppies, and agricultural products generally, and the

FIG. 2.—MARCGRAVIA PARADOXA.

ever, puzzled to understand why these poets sing of the Rose so enthusiastically—by all accounts of modern travellers the Rose gardens of Persia are simply fields of Roses and very unpoetical to look at. The air is heavy with perfume, and their cultivation is attended with considerable toil; a labourer among Roses is much the same as a labourer amongst Beans or Turnips, i.e., a most prosaic and unpoetical personage.

In St. John's travels in Egypt and Nubia he speaks of the Rose gardens at Medinet not adding to the

soil being cultivated to a depth sufficient to produce an amplitude of dust. It is impossible here to be poetical, and in a very few hours the cool *salon* with a refreshing *table d'hôte* [including a prime bottle of La Rose. Eds.], free from dust, clean, and with a quiet mind, the poetical instinct becomes much more satisfied than in the sight of Roses, however abundant: I have therefore still to seek the realisation of the fancy of seeing a Rose garden in all its beauty.

My ideal Rose garden must be somewhere in the "Midi" of France—a nook surrounded by trees to give

M. Thiebault, Minister for War; and M. Beernaert, Minister for Public Works. The absence of the Minister for Justice was noted. M. Delcour, Minister for the Interior, after having saluted his colleagues, who looked at him with a very puzzled air, expressed himself in these terms:—

"Gentlemen, pardon me for having summoned you at this unseasonable hour, but a fact of extreme gravity has been revealed to me with regard to which Government must without delay take the most energetic measures. The country is in danger, gentlemen."

"All the Ministers stare at their colleague in dismay. "A revolution in Paris?" asks the chief of the Cabinet.

"Impossible," says the Minister of Foreign Affairs. "The news would have reached my department. It is the Liberals again."

"It has nothing to do with them," replies the Minister for the Interior. "The danger which menaces our country to-day is of a totally different nature. Listen to me, gentlemen. I have just been informed in an official manner that there are in Belgium three things—no, there are in Belgium three Doryphoræ. These three Doryphoræ are alive, and one of them is scouring the country at this very moment. Do you see the danger?"

"The Ministers look at one another with an astounded air.

"Heavens," murmurs the Minister for Public Works—"and my wife, who has set off for the country this very afternoon."

"Is it a venomous beast?" asks M. d'Aspremont.

"Yes, and it appears, moreover, that it runs very fast," replies M. Malou, with a jeering air.

"Ah, if we had only to do with a venomous animal," responds M. Delcour, "but only think that the Doryphora may be perhaps full!"

"Full of what?" asks the Minister for War.

"Why full of bad intentions probably," says M. Malou, still facetious.

"Let us have no joking in such serious circumstances, my dear colleagues," continues the Minister for the Interior. "The peril is real, I assure you, for in truth this Doryphora may be full, and then—"

"Full of what, then, *morbleu!*" interrupts the Minister for War.

"Why, full of eggs—do you not understand? The American journals have stated that a single Doryphora may lay sixty millions."

"Sixty millions?" cry out all the Ministers.

"What is that to us?" says the Minister for War.

"The figure is probably exaggerated, but suppose that we reduce it to 600,000, the peril is not less alarming."

"What harm can that do us?" insists the Minister for War, shrugging up his shoulders.

"And the Potatoes, then!" cries M. Delcour. "Have you forgotten the law that we voted two years ago against the fatal beetle which makes such ravages in America in the Potato fields? You know that laws have been made in France, in Germany, and by ourselves, to prevent its introduction with the tubers coming from the United States."

"Ah, yes—the Doryphora; I recal it to memory now," cries M. Beernaert; "it was in the month of February, 1875. M. Andrimont even showed us some in a box; it is an insect as large and as round as a Pea, yellow, with ten black lines."

"Pshaw! all this is only about an insect!" says the General Thiebault. "*Morbleu!* to have ourselves inconvenienced for a trifle like that. Let us go."

"At this moment enters M. de Lantsheere, Minister for Justice. He takes his place beside M. Malou, and, speaking aside to him—

"Are we again at the Secret of the Confession?"

"No," replies M. Malou, in the same tone; "the question is about the Doryphora. We have got the Doryphora."

"The Doryphora—good heavens! Is it a new malady?"

"No, it is an insect—a parasitic insect."

"A new parasite? We have plenty already."

"This one attacks the Potatoes."

"Ah!" says M. de Lantsheere, visibly relieved.

"My dear colleagues," resumes the Minister for the Interior, "I request all your attention. Pray listen to me. I have not exaggerated the gravity of the situation, I assure you. All our Potato fields are in peril. Besides, if the Doryphora spreads with us, our international relations will be compromised. It is clear to me that if the wretched insect multiplies in Belgium, Germany, France, or Holland, England will put us in quarantine. These countries will stop our exports rigorously at the frontier. Industry will perish of plethora. It is already very ill, alas!"

"As a peg of consolation we shall, at least, have no more of the Spectre of Annexation," insinuates M. Malou.

"That peg scarcely consoles me," continues M. Delcour. "I would prefer the Spectre of Annexation. But let us return to our escaped Doryphora. We must retake it again without delay before it gets the key of the fields. It is at Glain that the insect now is."

"Do you believe that the Doryphora is still in that village?" asks one of the Ministers.

"It is probable," replies M. Delcour. "I have good grounds for thinking so."

"In that case I know a remedy," says the Minister for War.

"Speak, General!"

"You say that a great national interest is at stake."

"Yes; very great!"

"And this . . . Doryphora is still in the village of Glain?"

"I believe so."

"Very well. I make it my business; it is in my department."

"What is your project?"

"Burn Glain."

"And its inhabitants?"

"It would be wise to burn all; but they might at the utmost be forewarned, and made to leave before the execution, first submitting them, of course, to a rigorous examination."

"The remedy would be efficacious, but it is too military," observed M. Malou.

"Have you not said that a great national interest is at stake? For great evils great remedies!"

"It is so, but the remedy is too military," reply all the Ministers.

"I am amazed at you, and cannot understand your backward scruples. You do not keep pace with the progress of civilisation. We now do many worse things in time of war."

"But we are in time of peace," remarks the Honourable M. Delcour.

"That is why I would not burn the inhabitants with the village," sharply replied M. Thiebault. "I am not one of those Generals who . . ."

"It would be efficacious, but it is not feasible," interrupts the Minister of the Interior. "We should be subjected to hostile criticism. The newspapers of the Opposition would not fail to turn it to profit against us. They would be capable of likening this proceeding to the Inquisition, St. Bartholomew, and the like. No, no! It would be better to run the risk of the Doryphora."

. . . But there are other means. One might institute an active search," says M. de Lantsheere. "Arouse the zeal of the population by the hope of a large reward," proposes M. Beernaert.

"That is it; put a price on its head, as we did for Oblin."

"But it has no head," objects M. Malou. "M. Beernaert said just now that it is round, like a Pea."

"I said it was round, like a Pea, it is true; but it must nevertheless have a kind of head, or something which does instead of it, since it has a mouth—and it has a mouth, since it eats Potatoes."

"That is no reason," murmurs M. Malou. "There are some animals which eat, although they have no head."

"That is rather too much," said the Ministers, looking at their colleague with a distrustful air.

"But oysters and mussels, for instance," continues the chief of the Cabinet, "they eat, although they have no head."

"The discussion is beginning to wander from the point, gentlemen," interrupts the Minister of the Interior, "let us return to the question, if you please?"

"Has the Academy been consulted?" asks M. Malou.

"Faith! no one thought of it," replies M. Delcour; "but we are sufficiently competent in our bureaux; we will do without its advice. Besides, time presses. I return to my proposition of a few minutes ago. What do you think of a prize of a rooo francs to whoever succeeds in placing his hand upon the fugitive. The figure is high, I allow, but it cannot be concealed that a great national interest is at stake."

"All the ministers approve."

"It is then decided," continues the Minister of the Interior, "I will occupy myself without delay about this affair; it is necessary that from this evening a notice, promising the reward in question, be printed and posted up at Glain. There only remains one point to be settled—to which budget shall we impute the expense? Mine has no provision for anything of the kind."

"It appears to me," says the Minister of Justice, "that it should be to the chapter of agriculture, which concerns the department of the Interior."

"My credit is exhausted," objects M. Delcour; "besides agriculture (the dictionary of the Academy says so)—agriculture is the art of cultivating the earth; it has for its object production and not destruction. The Court of Accounts would refuse the payment. But your budget, my dear colleague, has formally provided for the case; I see figured there, at article 59, 80,000 fr. for measures of pubic safety."

"That refers to measures against foreigners," said M. de Lantsheere.

"That is it," said M. Malou: "that is it precisely! The Doryphora is a foreigner; it introduced itself into our country without a passport, and without being provided with a permission to stay here."

"Unanimous consent. It is nearly ro o'clock. The Ministers rise."

gardens, those tilled by the labourer and his family as a recreation from severer toil, or as furnishing a welcome addition in money or in kind to his store. But if this be so the author has greatly expanded his plan, as many of his directions are adapted to gardens of larger dimensions, and where the recreative element is the main consideration. Indeed his book is, as it seems to us, much better adapted for what it is now the fashion to call villa gardens than to cottage gardens proper, *i.e.*, the gardens attached to the cottages of the labouring poor and artisans. Looking at it, then, as a book for villa gardens wherein the proprietors do the greater part of their own gardening, with or without occasional assistance, it is entitled to our hearty commendation. The directions are clear and sensible, and the lists well selected. Here is a judicious hint about the pruning of fruit trees:—

"In pruning old neglected trees there is a temptation for the sake of uniformity of appearance, to saw out all old spurs, especially in the case of wall or other trained trees; but this is work that should be done very gradually, and spread over several years—that is, if the trees have been bearing fruit principally on the old spurs, which is generally the case. I have known instances where, for the sake of neatness, old spurs have been removed from old Pear and Apple trees, and the crop of fruit has been lost for several years in consequence. The old spurs seem to have arrested the sap, and to have converted what would otherwise have been wood-buds into flower-buds, and when they were removed the pent-up sap rushed into soft watery spray, and the trees became practically barren till the roots had been somewhat shortened. Neatness and uniformity in a fruit tree are doubtless very desirable, but the main object of the cultivator should be to obtain plenty of fruit of good quality, and to accomplish that result there must not be an excess of pruning with either knife or saw. Cutting out large branches ought seldom to be necessary, even in large standard trees, if the trees had been properly managed, and the thinning gradually attended to when the branches were small. There are two main objects sought to be obtained by pruning. The first is to build up a well-balanced, healthy, vigorous tree in as short a time as possible; and the second is, in conjunction with the first, to encourage the production of fruit-buds, so as to bring the tree into a bearing condition as early as is consistent with its permanent well-doing. A well-balanced tree can easily be secured by heading back at the autumn pruning any branches not sufficiently furnished. But fertility is best obtained without much use of the knife. Disbudding or thinning out the young growths early, when the trees are producing too much soft spray, should be followed in due course by a gradually progressive pinching back through the summer, and every tree should be treated separately, without any reference to its neighbours. Root-pruning is a valuable expedient to adopt in the case of trees excessively vigorous that are not easily subdued by any other means; but with all trees of a manageable size the object sought is best attained by digging the tree up carefully and replanting it. This usually gives sufficient check to moderate the growth, and bring the trees into a bearing condition. October and November are the best months for this operation, and also for the shortening back of a few of the roots of any large, strong-growing tree that may be too large to lift and replant. In nearly all cases, if half the roots be shortened back, the check given will have the desired effect, there being a danger of permanently crippling the tree should the roots be too severely pruned. In some cases opening a trench on one side of the tree at about 3 feet from the trunk, and working under the ball so as to get at the roots that descend perpendicularly, will be sufficient. When those are severed the hole may be filled up again, and the soil made firm."

— SUNDAY LAST must have been regarded by gardeners, near London, with much more complacency than it probably was by young ladies, or farmers with their hay about. After a long spell of drought, with at times almost tropical heat, and as often of keen, drying, withering winds, all vegetation was late and delayed by the absence of rain, the ground was hard, literally baked with the heat, crops suffering, Potatoes yet unearthed and waiting for the necessary rain to pulverise the rough lumps and soften the soil. With these drawbacks to the season it will be well understood that the truly model day's rain that then refreshed the soil, washed the coating of dust from vegetation, and gave a hue of freshness to plants to which for some time they had been strangers, was trebly welcome to gardeners who were within range of the refreshing change. Potatoes, late Peas, Beans, and other vegetables will immensely benefit, whilst it has proved a veritable god-send for the getting out of winter green crops.

Notices of Books.

Cottage Gardening. By E. Hobday. Macmillan.

What is a cottage? It is obvious that the answer must be a comprehensive one, and unless some less vague and more precise definition be given as to what the author means by a cottage, it is difficult to form a fair judgment of his book. From incidental remarks we infer that the original intent of the book was to provide information for the smallest form of cottage

Garden Operations.

PLANT HOUSES.

GREENHOUSE HARD-WOODED PLANTS.—Young stock that have been recently potted should not for two or three weeks yet be exposed to the sun without slight shading some half dozen hours during the middle of the day. When the weather is extremely bright and the atmosphere dry, such as where no rain has fallen for some time, all young growing stock will be better for a thin protection this way where the houses in which they stand are constructed so as to admit a maximum of light; this is especially the case if the structure happens to be a lean-to facing the south, which from its position is subject to the full influence of the sun in the hottest part of the day; in old houses, the roofs of which consist of heavy timber and small glass, it is different, and little or no shade will be needed by established plants. To achieve anything like success in plant cultivation it is necessary to discriminate in this way in the requirements of the various things grown under different conditions. In hot weather during the middle of summer the floor under the stages, generally consisting of either the natural earth or other material that will absorb moisture, should be thoroughly soaked with water once every ten days or fortnight; this will beneficially affect the plants in several ways, through the humidity it imparts to the atmosphere of the house, accelerating growth and enabling them to better withstand the effects of sun at a time when at its greatest power; it is also one of the best preventatives against the attacks of red-spider. All plants, but especially large specimens, should be turned round every week or ten days, where this is necessary to admit of the water in syringing reaching every portion of their leaves. When plants have been stood in lean-to houses where they can only be got at from one side, through not attending to this matter I have frequently seen the half non-accessible to the syringe seriously affected with red-spider, and though there are those who look upon its presence as a matter of no great consequence, yet if ever hard-wooded evergreen plants get infested with it to any considerable extent, they rarely afterwards can be brought into condition equal to those that have not suffered in this way. *T. Baines.*

ORCHIDS.—Plants of *Dendrobium Falconeri*, whether on blocks or in baskets, must now be well supplied with water at the roots, as well also as being frequently syringed overhead, among the young lateral growths, and the fine threadlike roots that start away from them. This latter operation is the more important, and must not on any account be neglected, for hanging down from the roof, as it is generally met with, the roots do not get half the nourishment they require, and consequently the breaks do not exhibit the strength and vigour that under a genial and more liberal treatment they may be enabled to do. There can be no doubt that the best way to treat this, and the one that will bring about the most satisfactory results, is that of growing them in pots, as described in page 689 in your last year's volume v.; and to any who have this in a poor and inferior condition I should say, place it in a pot with but a small quantity of peat and moss about the roots; tie the shoots up about half their length, the remaining part being tied round so that the plant may have more of the appearance of a hard-wooded plant. The plant should now be stood on the side-table of the *Dendrobium*-house, the syringe frequently used, and not at present subject to much strong light. As the growths push away tie them out, always keeping the points turning outwards, and in a short time the plants will assume a state of freshness and health that cannot be so readily obtained on the hanging-down principle. Few plants when first imported look more unsightly and seem to hold out less promise of future success than the *Dendrobiums*, taking them as a whole; at the same time it may truly be said that there are scarcely any that under genial treatment will in the same short space of time, by new growths and healthy green leaves, hide all that is unattractive, and assume an appearance of health and vigour and pleasing progress. When a number of these are obtained—and so much the better and the greater certainty of ultimate success when they are received in the early spring, there being then the whole of the season before them—they must as quickly as possible be attended to, so that by syringing and a gentle heat the old bulbs may again be filled up with a healthy sap, and thus, as it were, a reserve will be ready when the young breaks push away, which, in some degree at least, in the earlier stage of their growth, depend upon the old bulbs for their stay and support. Those of the long bulb section, as well also as *densiflorum*, *thyriflorum*, &c., should be grown in pots, they being more handy for moving about, whilst such as are shorter in the stem, or of a decidedly pendulous character, must be put in baskets or on blocks. Many of these plants will be resting from growth for at least six months of the year, during which time the formation of bloom-buds and the ultimate flowering process

comes on; and though in the increasing of the size of the plant this resting period may appear the least important time, there can be no doubt that a proper and consistent method of treatment during this period is just as important as a well-regulated season of growth. *W. Swan, Fallowfield.*

FRUIT HOUSES.

ORCHARD-HOUSE.—Where mixed fruits, including Cherries now ripe, are grown in districts infested with birds, Chiswick netting or some other light material must be placed over the ventilators, otherwise they will soon spoil the crop; but the most satisfactory plan is to remove the Cherries to a partially shaded, airy spot, where, protected with old lights for throwing off wet and netting round the sides, choice Cherries may be kept in good condition for several weeks, and this arrangement admits of giving the permanent occupants of the house the full benefit of unimpeded ventilation by night and by day. The necessary thinning and mulching having been brought to a close, the most important operations will be vigorous syringing twice a day and liberal supplies of liquid manure diluted with tepid water. Attend to the stopping and training of young growths, and observe former directions with regard to the extermination of insects, particularly the black-fly, as these pests are extremely hard to kill when thoroughly established in the points of the shoots. Keep down red-spider by means of good syringing and occasional use of the garden engine. Examine borders which may have become hard on the surface and impervious to the free passage of water, break up the soil a few inches deep, add fresh mulching, and give repeated waterings until every part occupied by the roots is well soaked through, as Peaches and Nectarines in a growing state, if well drained, cannot be over-watered; indeed, half watering is the most fertile cause of dropping; and the premature ripening of our finest stone fruits. *W. Coleman.*

CUCUMBERS.—Plants in pits and frames which have been some time in bearing, may now be cut and dressed over more severely than usual, as they show signs of exhaustion. After the removal of old bearing bines and leaves, the bed should be well soaked with lime or soot water for the destruction of worms, preparatory to the top-dressing of 2 to 3 inches of good firm turfy loam which is to follow. Let the turf be well packed in amongst the stems, and peg the young growths down quite close to the soil. Water overhead, and keep close for a day or two, until the leaves have recovered their position and young roots are seen working into the new soil, when the usual treatment may be followed. Watch closely for greenfly, and fumigate as soon as it is discovered. Give copious waterings with tepid liquid manure twice a week. Water overhead on fine afternoons, and crop lightly if clean straight fruit is held in favour. A few seeds of Telegraph may now be sown for early autumn fruiting. Allow four weeks for the plants to become strong and fit for turning out. Meantime make the necessary preparations by thoroughly cleansing the pits and getting together suitable materials, such as tan or leaves for producing bottom-heat, as these will produce a more genial medium for the roots than hot-water pipes. Use turfy loam somewhat stronger than that recommended for general winter work. Drain the beds or pots well, and insure sturdy growth by ventilating freely, shading slightly, and early closing with plenty of moisture. *W. Coleman, Eastnor.*

STRAWBERRIES IN POTS.—The runners from these plants will evidently be somewhat later than they are in some seasons, a fact itself alone sufficient to indicate the necessity for pressing forward at the earliest moment the process of layering on young vigorous plants which were planted out last season, and on those which have had special treatment for producing runners alone there will now be a supply fit for the operation. For this purpose use moderately rich soil which has been passed through a coarse sieve beforehand, which, with the runner, should be pressed firmly into medium 60-sized pots and fixed by means of a small peg or stone, and be watered afterwards. To save time and attention to watering many plunge the pots into the soil; for the later kinds this is a very good way, but for the earliest required plants, when speedy root-action is so desirable, time will be gained by exposing the pots to the action of solar heat, providing the requisite degree of attention be given to watering regularly. In order to accelerate an early development in those plants which are intended for early forcing operations, avoid the use of large fruiting pots, those of from 4 to 5 inches diameter being ample for the purpose. In potting these the crown of the plants should be kept well up above the surface of the soil. To prevent the buds from sustaining injury from dampness at the advanced period at which these will appear, after potting well water the plants, place them in a shady place for two or three days, and then stand them in a position where every ray of sunshine

will operate freely, and which has been prepared for them by means of ashes to resist the inroads of worms to the pots. As it is very important to get all these plants well established betimes, no delay should take place in potting them into the fruiting pots as soon as the plants are fit; in every case pot the plants firmly into moderately rich and rough soil, and for strong-growing late kinds 6-inch pots may be used. *G. T. Miles, Wycombe Abbey Gardens.*

KITCHEN GARDEN.

With so late a season it may be feared that the cutting of Asparagus has, of necessity, been protracted beyond the usual time, but as there should now be a continuous supply of Peas the cutting should have been entirely stopped a week ago, and as the present is the season when it will be best to apply a large amount of stimulants in order to strengthen the roots for another season's bearing, the operation may be at once commenced by applying salt in the proportion of about a pound to the square yard; this, besides acting as a very beneficial manure for the plants, is thoroughly destructive to weeds of all kinds. After a week or two, and during wet weather, a good dressing of guano will be a fine supplemental stimulant. With such aids as a powerful sun and the dry season the hoe is one of the most useful of implements, and, if kept constantly in use amongst advancing crops, will do much to ward off the serious effects of drought, as well as keeping down the seedling weeds. This operation is especially imperative in gardens having a strong retentive soil, which is apt to cake on the surface and split up in large open cracks which admit the drought deep in the earth, and a well-regulated system of surface-stirring is the best method of preventing evaporation. The earliest planted Celery may now have occasional applications of liquid, but the main crop will scarcely be sufficiently rooted for much stimulation, and only copious applications of water should be applied. Continue to plant more trenches of the same for later successional purposes. A good breadth of Walcheren Cauliflower from the latest sowings should be planted on a well-manured border; if facing the north, so much the better. The white and purple Cape Broccoli should also be got in at once, and if not already done, another lot from the last sowings of Veitch's Improved Broccoli and Autumn Giant Cauliflower should be got in to succeed the earlier plantations; the latter will only show its true character in highly-manured soil. The plantations of hardy spring Broccoli and Winter Greens must be followed up as ground becomes vacant for the purpose; in fact, there should not be any vacant ground now—every corner and available space should now be planted with something likely to be useful in the future, and as soon as a crop is taken off the space should be immediately filled up; but this system of continual cropping can only be successfully carried out where there is a good supply of manure, without which tender and succulent vegetables of most sorts cannot be secured. Successional sowings of various sorts will still be necessary, in order to maintain a continual supply: a sowing of Cabbage for autumn use and of the various sorts of Lettuce will be necessary, as well as continual sowings of Radishes and small salading. A good breadth of Turnips for autumn should be sown at once, and advancing crops thinned out and copiously watered where possible. A late sowing of dwarf French Beans of an early sort may be tried, but they must have a warm and sheltered situation. Scarlet Runners should be well staked, and the bine assisted with a little tying at first, to give them a fair start up the rods. A last sowing of Peas may be tried, for which purpose *Ne Plus Ultra*, *Knight's Tall Green Marrow*, or *British Queen* are suitable sorts; they must be sown in trenches, with manure dug in the same as prepared for Celery. Frequent waterings and mulching must also be resorted to, and watering and mulching will also be necessary for all the later crops, which should always be staked in time. Where any of the taller sorts are becoming top-heavy it is a good plan to drive in some stout stakes at intervals along the rows, and pass a length or two of rope yarn from stake to stake along the rows: this will afford sufficient support for the Peas, and at the same time not much footing for those little destructives the birds, always so troublesome to the late crops. Beds of ridge Cucumbers and Vegetable Marrows must be kept trained out, stopped, and frequently watered. See that the ground is stirred amongst beds of Onions, which are not so strong this year as usual—if very dry a good soaking of water in which a small proportion of washing soda has been dissolved will be beneficial, which solution will also have the effect of keeping the Onion maggot in check. Thin out the later sown Carrots, and give them every encouragement to grow out by frequent surface stirring. Basil, Chilies, and Capsicums under south walls will require attention in watering and tying up, and see that Tomatoes are kept thinned out and fastened. Now is a good time to commence the preparation of manure for making up Mushroom beds in the open air next month, *John Cox Redleaf.*

THE
Gardeners' Chronicle.

SATURDAY, JULY 7, 1877.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY,	July 9	Sale of Natural History Specimens, at Stevens' Rooms.
TUESDAY,	July 10	
WEDNESDAY,	July 11	Sale of Orchids, at Stevens' Rooms.
		Royal Caledonian Horticultural Society's Summer Show.
		Ealing, Acton, and Hanwell Horticultural Society's Show.
		London Horticultural Society's Show.
		Enfield Horticultural Society's Show.
		Bristol, Clifton and West of England Rose and Strawberry Show.
THURSDAY,	July 12	Newcastle-Tyne Botanical and Horticultural Society's Summer Show (two days).
		Higgate Horticultural Society's Show.
FRIDAY,	July 13	Ludlow Rose Show.
		West of Scotland Rosarian Society's Show, at Helensburgh (two days).

PUBLIC attention is very properly being called to the COLORADO BEETLE, and to the best means of dealing with it. We have done our part in bringing the matter before the practical growers, and are pleased to see that the general Press is becoming aware of the gravity of the situation. Since our last issue the appearance of the insect near Mülheim has been confirmed, and our German friends seem to have "taken the bull by the horns" in a way which ought to be efficient. Sawdust saturated with petroleum was scattered over the field, and the whole set fire to. Such a procedure would in all probability destroy eggs, larvæ, and beetles, together with the Potato haulm, and therefore at the sacrifice of the tubers. No doubt this stamping-out process is the best in the first instance, when the pest is limited in its range, but we question very much if the English Potato grower would at once see the necessity for such a step—he would be sceptical, or he will procrastinate till the beetle has got a footing—till the eggs are deposited broadcast on the leaves, and not till he sees the fat larvæ stripping the leaves before his eyes will he begin to exert himself; then probably the application of Paris-green, as recommended in our last number, will be the best remedy, and one which at any rate gives some hopes of the crop not being utterly destroyed. The eggs, we are told, take six days to hatch; the larvæ or grubs live for about a fortnight prior to assuming the pupa or chrysalis stage, in which state the insects remain for another nine days before assuming the condition of full-grown winged beetles.

At the Royal Horticultural Society on Tuesday last Mr. ANDREW MURRAY exhibited specimens of the insect in various stages, together with enlarged diagrams showing its structure and appearance. Mr. MURRAY also gave a brief account of the habits of the insect, showing that it extended as far as its natural food plant, *Solanum rostratum*, the plant itself being distributed by means of buffalos, to whose hairy hide the prickly calyx of the plant adhered. From the wild plant it passed to the Potatoes of the cultivated regions, spreading from field to field in the way familiar to our readers, from the reports given of its rapid progress from the West to the Eastern States of North America. It was unfortunate that so small an audience was gathered together to hear this interesting communication, but no previous notice had been given; and even if it had been, the conservatory of the Royal Horticultural Society on a meeting day is probably about the worst place possible for such a purpose. Still, this is one of the many ways in which the Royal Horticultural Society should render service, and prove its utility.

In face of so grave a danger, no doubt the Government will take every means that a non-paternal Government can do to spread information as to the appearance of the beetle, and the best method of coping with it. The eggs

should be destroyed wherever seen, and a sharp look-out kept for the long, bulbous-bodied, spotted larva on the haulm. It is the larva which is most destructive, but the powers of flight and the egg-depositing tendency of the female fully-developed beetle more than compensate for its smaller appetite.

We regret also to have to record the re-appearance of that peculiar form of the POTATO DISEASE which created such interest two years ago, and in which Mr. WORTHINGTON SMITH first discovered the resting-spores of the fungus. This form of the disease has again appeared at Chiswick, and in American varieties, but not wholly. Some of the affected plants, moreover, have, we believe, been dressed with Salus. From other quarters, too, we hear of the outbreak of the disease, so that the prospects of the Potato crop do not seem very bright at present. Let us hope anticipation will, as is often the case, prove worse than the disease.

WHAT a wonderful place this London is. What a hold on the affections the garden, and, in particular the Rose, has. Such might well be the reflections that passed through the minds of enthusiastic horticulturists on Wednesday last, the programme for that day included the great exhibition of the National Rose Society, the dinner of the enthusiastic rosarians, the anniversary dinner of the Royal Gardeners' Benevolent Institution, an evening *fête* at the Botanic Gardens, Regent's Park, besides private garden parties and entertainments of which we can take no heed. In what capital of the world could such a programme possibly be carried out in one day? There might have been a few, perchance, gifted with endurance like that of His Majesty of Brazil, who assisted at all the ceremonies in question. But perhaps the most astonishing fact of all, as showing intense devotion to the Rose, is the circumstance that not one or two, but numbers, came from Cornwall, from Devonshire, from Herefordshire, from Scotland even, travelling all night their 200 and 300 miles, in the morning to worship at the shrine of Rosa in the morning. "A matter of business," some will say, and, of course, to some extent it was so. The great commercial rosarians were naturally present in numbers, but our remarks apply to the country parson, the village squire, and others whom no inducement save that of love for the Rose drove from their homes on that memorable day. Arrived at the scene of action, many had work to do in staging, and, subsequently, in judging the Roses, so that a luncheon was a desirable thing enough. Nor, some hours later, was a dinner at all unacceptable to the zealous rosarians, who dined together under the presidency of the Rev. Canon HOLE.

At this dinner the "Health of the Chairman," proposed by Mr. BAKER, drew forth some pertinent observations and suggestions, in the course of which Mr. HOLE remarked that his experience of thirty years as a Rose grower taught him we had much yet to learn before we should bring out the Rose in all the perfection of beauty it was capable of reaching in our climate. He thought that the use of the seedlings and cuttings of the Brier as stocks was a great improvement, imparting hardiness and vigour to the Rose; but his own observations led him to the conclusion that Roses on their own roots would prove to be the most satisfactory, and that it was in this direction that perfection must be sought. An expression of opinion on these matters being invited, Mr. G. PAUL objected, preferring to bud low and plant deep, by which he maintained there was received—first, the impetus derived from the roots of the stock, and then the further support and permanency to be derived from the natural roots afterwards produced from the budded portion.

These and similar matters, it was suggested might be discussed with much advantage to, the Rose-growing community in the *Transactions* or *Journal*, which it was part of the scheme of the founders of the Society to publish (perhaps half-yearly) as soon as circumstances permitted.

In another part of the town, the great hall of the "Albion" was filled with a large party of diners, in the cause of charity and benevolence. We were glad to find that some managed to follow out our suggestion to lunch with the Roses and dine with Benevolence, but it could not be expected that even a rosarian could eat two dinners in one day, so that the party at St. James' Hall and that at the "Albion" was composed of different elements. Had benevolence not been very well supported we should have been disposed to complain of the specialists for putting their hobby in the way of the fulfilment of what ought to be an imperative duty with all horticulturists, viz., the support of any institution devoted to such ends as the Gardeners' Benevolent. As it was, however, the body of Horticulturists with their friends and supporters was large enough to fill both rooms, and if the Rose Society has a sufficient surplus, the best thing they can do with it is to wipe out the memory of their unavoidable secession by handing it over to the Institution in question. Sir TREVOR LAWRENCE, who took the chair at the "Benevolent," in the course of his speech alluded to the great advance in horticulture, and to the great extension in the taste for horticultural pursuits, and cited as evidence the beautiful condition of the garden beds in Hyde Park, Battersea and Victoria Parks, and others. Compare their condition twenty or five-and-twenty years ago with what it now is, and the appropriateness of Sir TREVOR'S remark will be apparent. The Chairman also commented on the great things that have been done in India, in the introduction and cultivation of Tea, Cinchona, &c.—a truly great work, carried out mainly by British gardeners. Sir TREVOR LAWRENCE was not content with presiding, he contributed greatly to the embellishment of the room by bringing some fine Orchids, and in particular a noble specimen of *Oncidium crispum* growing *au naturel* on a forked branch and surrounded by Ferns and small climbing plants—a delicious bit of Nature in the heart of a City dining-room! The company was, as we have said, very numerous, comprising many of our best known horticulturists.

What happened at the Botanic *fête* we cannot say, from personal experience. Our porters might well be pardoned after such a day's work if they eschewed a *fête*, which was of fashionable rather than of garden interest.

— WE present our readers this week with a COLOURED ILLUSTRATION representing a group of Roses, drawn from Nature by the eminent botanical artist, W. H. FITCH, and executed for us in chromolithography by M. SEVEREVNS, of Brussels. Should the plate become creased in transit through the post, the reader is recommended to lay it face downwards on a sheet of clean paper, then damp the plate on the plain side, place another sheet of paper over the moistened surface, and on the top of all a heavy hook or weight. In a few hours all creases will be removed.

— In responding for the Fine Arts at the WILSON DINNER on Tuesday, Mr. HARRISON WEIR dwelt on the value of wood engravings, not merely as affording gratification to persons of culture and refinement, but as a great power of teaching and persuading the masses of the people for their good. He somewhat startled his hearers by stating that about five million copies of engravings from his drawings were circulated annually. Mr. C. P. SLOCOMBE of the South Kensington Art Schools spoke of the immense benefit the schools derived from their proximity to the gardens of the Royal Horticultural Society, and the consequent freshness and variety of the plant-subjects supplied from the gardens for the use of teachers and pupils in the schools. He said he must regard Mr. BARRON as one of the best friends of Art, for he was

ever ready both to meet their wants and also to suggest subjects they might not think of for themselves. From his point of view, therefore, said Mr. SLOCOMBE, the connection of the Society with South Kensington was to be regarded as eminently beneficial.

— It was stated in our last issue, at p. 280, that *FREMONTIA CALIFORNICA* does not thrive in the open, and that the wall is its true position. To prove that this is an error, Mr. PARKER, of Tooting, exhibited flowering branches at the meeting of the Royal Horticultural Society, on Tuesday last, cut from a bush which has stood in the open air in his nursery unprotected for several years, and which is about 5 feet high and 7 feet in diameter. The fact is one of importance, inasmuch as it greatly enhances the value of a very beautiful plant.

— There seems to be considerable difficulty about the cultivation of the varieties of *IRIS KEMPFERII*. In the window of Messrs. BARR & SUGDEN might lately have been seen a fine group of these singular and beautiful forms. Mr. BARR's experience is that the plants must be established in good *Rhododendron* soil. It is much to be wished that those who have succeeded in propagating and flowering this fine race should make public their observations.

— While the florists' varieties of *Fuchsias* are increasing with rapidity, and generally in new and improved forms of beauty, there are some of the species that are so attractive from the decorative point of view, and so well suited for the embellishment of the conservatory, it is a pity they command so little attention. There are the old *Fuchsia fulgens*, and the dark-leaved variety of it Mr. BARRON grows at Chiswick; *F. corymbiflora*, and *corymbiflora alba*; *F. pumila*, *F. globosa*, *F. microphylla*, *F. spectabilis*, and *F. Dominicana*; and to these may be added Mr. LAING's new hybrid *Earl of Beaconsfield*, which makes a fine exhibition variety; *Sedan*, with its red tube and sepals, and dark carmine-rose corolla; *albo-coccinea* and *Germania*, all of which are quite distinct in character. Such a group as this varies the type of flower considerably, and adds much to its interest. *F. Dominicana* is particularly an autumn and winter flowering species, but when planted out in a conservatory bears flowers almost all the year round.

— At the Scientific Committee on Tuesday last an interesting fact was made known, viz., that the first botanical publication of Dr. LINDLEY was a description of *MARANTA ZEBRINA*, in the *Bot. Reg.* 1819. The fact is attested by a note in Dr. LINDLEY's handwriting.

— Season after season we hear that measures are being taken by the anxious Swiss against the threatened extinction of the *EDELWEISS*. With the exception of the *Alpenrose* no other mountain flower is so characteristic of the alpine districts, so popular among foreign visitors, and so dear to the native heart. The poems written upon these two plants alone would fill a big volume. All tourists of culture, says the *Echo*, quite as anxious as the Swiss themselves can be that this unique plant should live on to future generations, and afford delight to botanists and climbers who are yet unborn. Some of the foreign Alpine Clubs have done what they could to put a stop to the present reckless and culpable waste of the *Edelweiss*. We believe that the members of the Austrian Alpine Club a year or two ago issued a bye-law against the custom of wearing a sprig of the flabby *Gnaphalium* in the hat. The communes of the Upper Engadine have now taken the flower under the protection of their local civil law, and the sale of the plant in its fresh and living condition is prohibited, under the penalty of a fine of 5 f. for the first offence. The proposal was started by the Kurverein, an association which seeks to make life agreeable to the thousands of health seekers and pleasure seekers who, during the summer and autumn, sojourn at St. Moritz, Pontresina, Samaden, and the other villages of which the famous waters of St. Moritz are the centre. The proposal was unanimously accepted by the august senators of these venerable little republics of the Grey League. It appears that the worst persecutors of the plant are the Italians, those picturesque Bergamo herdsmen and herdboys who come up from the southern side of the

Alps at the beginning of the season, and remain on the mountains with their flocks until the first snow falls. They pluck up the flower mercilessly by its roots; and they will run beside a carriage for half a mile entreating and almost commanding the inmates to purchase a bunch, lowering the price of the proffered article at every few yards, until they force the traveller into purchasing by wearing out his power of saying "No."

— The fine *DOUGLAS FIR* at DROPMORE is now 111 feet 6 inches high, and about 12 feet in girth round the bole at 5 feet from the ground. It has suffered a little from the effects of snow and wind last year, but is still a tree of grandest proportions. The famous *Araucaria* is in good condition.

— In his report on the condition of the Royal Gardens, Kew, for 1876, Sir JOSEPH HOOKER calls attention to the rapidly progressing destruction of the beautiful "eyot" in the Thames, opposite Kew Bridge. When it is remembered that this beautifully wooded islet shuts out the view of the soap-boiling works and other abominations of Brentford, it will be acknowledged that it is high time steps were taken to preserve one of the most beautiful "bits" on the Thames.

— Is it generally known that *TURKEYS* prey upon *SNAKES* when they have the chance? They do so at Cliveden we are assured.

— A botanical *fête* and musical promenade will be held in the Pine-apple Nursery Grounds, Maida Vale, by the kind permission of Messrs. E. G. HENDERSON & SONS, on Thursday evening, July 12, 1877, in aid of the fund for the enlargement and improvement of St. Mark's Church, Hamilton Terrace, N.W.

— From various sources we learn of an increasing difficulty in cultivating *HUMEA ELEGANS*. How or why is this? Can any correspondent confirm, refute, or explain it?

— A circular has been issued by the Rev. F. D. HORNER, the Hon. Sec. of the NATIONAL CARNATION AND PICOTEE SOCIETY, to growers and members of the Society, for the purpose of ascertaining their willingness to consent to the postponement of the show from the last week in July to the first week in August. On Saturday, August 5, there will be held, at the Botanical Gardens, Old Trafford, an exhibition of cottagers' produce, window plants, &c., under the auspices of the Manchester Botanical and Horticultural Society; and it is the desire of the Council that the National Carnation and Picotee show should be held in conjunction with this exhibition. If it can be arranged, the Council will give the sum of £10 towards the Carnation Show fund, and provide accommodation for the visitors. This arrangement appears so reasonable that it is to be hoped it will be carried out, especially as there is reason to believe the flowers will be in bloom later than usual this year. The Manchester Society has extended such generous support to the florists of the North, that we are sure any suggestion from the Council will receive the full consideration it deserves; and there is every reason to believe the proposed arrangement will be carried out.

— At Dropmore, the other day, we lighted on a plant of the old *PELARGONIUM TRICOLOR*, an old-fashioned bright-flowered gem almost lost sight of. We mention it now in connection with the curious piebald *Pelargonium*, half white, half scarlet, shown at a late meeting of the Royal Horticultural Society by Messrs. SMITH, of Dulwich. The object of the diversity in colour in the wild flower is to serve as a guide and signpost to insects, which are by its guidance induced to visit the flower where they can best get the honey, and where at the same time their aid is most efficient in fertilising the flower—a wonderful contrivance, the whole significance of which is lost by the average florist.

— What is known as CARTER'S HEARTWELL CABBAGE is a quick, early dwarf variety especially deserving the attention of market gardeners and those whose gardens are restricted in space. It is a selection from the Early Improved Nonpareil, and has the

short compact growth of that variety, but in a remarkably compact form, and, with the exception of the outer circle of leaves, it is all heart. This estimate of the Cabbage is drawn from inspecting a large field of it in the occupation of Mr. HENRY DUNNETT, at Ardeleigh, and the remarkable evenness of character of the crop is at once apparent. It can be particularly recommended to those having a small space of garden, and where every square foot of ground is a consideration.

— Just now, when the spring bedding is over, and the summer beds are only just planted, there is a dearth of flowers in the flower garden, which may be well obviated by the use of the MONTHLY ROSE. Some beds of this on the fine plateau at Cliveden are very lovely at the present time.

— JAPANESE TEAS appear to be getting greatly in favour in New York, where many fine kinds, both of Japanese and Chinese produce, find a ready market, owing to the quick transit the tea ships make. Through the agency of steam new crop teas find their way to New York much earlier than formerly, and the cargos generally arrive in fine condition. The general favour with which Japanese teas are being regarded is due to the deterioration of the Chinese product. The Japan leaf, unlike the China leaf, is prepared, or, in other words, fired and manipulated under the direction and at the establishment of the foreign shippers, principally English and American firms, at the ports of shipment. This tea was originally introduced into America as natural leaf, but through the enterprise displayed in its preparation to produce styles and colours peculiar to each shipper its original designation has become nearly obsolete. Some of the terms now used to describe it are "Kil-somina," "pale," "grey," and "blue." It is mentioned as a somewhat significant fact that the effort to introduce Japan tea into other countries has been unsuccessful, America taking the bulk of the quantity exported.

— Those who would see an OLD-FASHIONED FLOWER GARDEN in full beauty would do well to visit Dropmore at the present time, if fortunate enough to have the privilege of doing so. The display at this present time is made up principally of old *Roses*, *Rosa gallica*, the old white *Moss*, *indica*, *Maiden's Blush*, *Noisettes*, &c., together with double *Rockets*, *Larkspurs*, *Oriental Poppies*, *Gillias*, *Sweet Williams*, *Sweet Peas*, *Eschscholtzias*, *Campanula speciosa*, &c. Earlier there were *Narcissi* and *Squills* and grand *Tree Pæonies*; later there will be *Dahlias*, *Asters*, *Gladioli*, *Phloxes*, *Sedums*, and a host of other plants. No wonder people tire of bedding plants, ribbon borders, and carpet beds. There is far too much of them even now. On a lawn under the windows a few well-arranged and well-kept beds are in keeping with the architectural lines of the building, but the real flower lover will always prefer the old-fashioned flower garden with its never-failing supply of fragrant and lovely flowers, never quite the same for two weeks in succession. Granted it is not so trim as a series of well-managed mosaic beds, but that defect is far outweighed by the constant interest and variety. One can't be sentimental over a carpet bed, however beautiful, and one ought to be sentimental in a garden!

— Mr. MECCHI requests us to state that, owing to his advanced age the TIPTREE ANNUAL GATHERINGS will be discontinued, but he hopes that his brother agriculturists will come and inspect his crops before or during harvest.

— What a splendid flower is the old COPPER COLOURED BRIER. In the roserie at Valentines, or against a wall and in the open border, as at Dropmore, it is just now resplendent.

— Referring to the growth and PRODUCE OF THE VINE (*Vitis vinifera*) IN SAN FRANCISCO, a recent report says that wine produced "from the old Mission Grape does not find a ready market, even at a very low price, and the Vine growers are either by planting or grafting superseding it by the best foreign varieties, the result of which is observable every year in the manufacture of superior wines. The total exports of wine for the year amounted to over 1,000,000 gallons. The production of raisins is also

assuming some importance, 30,000 boxes, each of 20 lb., were produced in the State last year. The Muscatel, and one or two other varieties, are equal in every way to the best imported. Grapes can be grown at a profit at 1 cent per pound, and at this price raisins can be sent into the market to compete successfully with the imported article. Regarding other fruits, the crop of Oranges during the year was a partial failure. In Los Angeles county the produce did not exceed 2,750,000 against 5,000,000 in the previous year, but an immense number of trees, it is stated, will come into bearing in the course of the next two or three years.

— A stand of fifty FANCY PANSIES from Messrs. DOWNIE & LAIRD, of Edinburgh, intended for exhibition at the Rose show on Wednesday last, since they could not be there received, have since found their way to our office, and a very fine lot they were. The blooms were large, bold, richly coloured, and greatly varied, showing how eminently the climate of Scotland suits these fine spring flowers. We only regret, as they were not named, we cannot indicate which sorts were the best amongst them; but where all were good this is, perhaps, of less consequence.

— Few of the New World evergreens, which we are in the habit of calling American plants because received from America, are more beautiful than the *KALMIA LATIFOLIA* when growing in a situation which is congenial to it; and few situations, we should imagine, can be more congenial to it than the grounds at Bearwood, the magnificent country seat of JOHN WALTER, Esq., M.P. for Berkshire, judging from the appearance presented by it when we saw it there some week or two ago. The Rhododendrons and hardy Azaleas also grow with remarkable vigour at Bearwood, and annually present floral features of great beauty, which, with the liberality of a true English gentleman, Mr. WALTER throws open to the view of the residents in the adjoining towns and villages. The *Kalmias* when we saw them were particularly fine, and showed considerable variety as regards the tinting and arrangement of the flowers, some of the blossoms measuring nearly 1½ inch across, and all growing in massive trusses, which freely covered the surface of the plants. These beautiful grounds—which have undergone great changes during the past few years, bear witness to Mr. WALTER's fine taste—are freely varied by water and woodland and a boldly undulating surface. In the pleasure grounds are many handsome specimens of choice trees, notably of *Araucaria imbricata*, *Cryptomeria japonica*, *Picea Pinsapo*, and, last but not least, a fine seven-limbed Birch, the principal stems of which spring near the ground from one main stock, and cover a large surface of the mossy turf. In the park a prominent feature is an avenue of Wellingtonias, leading from the main entrance to the mansion; and a fine avenue of these trees, of considerable length, also planted by Mr. WALTER, on the roadside near the Wellington College, are doing remarkably well, and will soon form a prominent feature of the district.

— In addition to the fact that the recent inauguration of the CANTON EXHIBITION took place in the Royal Horticultural Conservatory at South Kensington horticulturists owe much to the art of printing, and therefore may well feel an interest in the proceedings on that occasion. Mr. GLADSTONE's address, delivered standing exactly opposite to the broad stone steps, was heard with singular clearness by the large assemblage; and most admirably did it illustrate the rise of printing in this country under the care and auspices of CANTON. What horticulturists did before the age of printing it would be difficult to say. Perhaps in those dark days horticulture scarcely existed, or, if it did, only in such crude forms as to be in keeping with the mediæval barbarism that marked the days of CANTON. Now we wonder less what was done without the art of printing in days past and more as to what we should now do without it. Printing, as represented in the horticultural press and in the many splendid books on gardening, both standard and serial, that have been put into circulation by its aid, is an art specially dear to horticulturists; and all will alike join in wishing a long and loving recollection of the first English printer.

— Messrs. JAMES CARTER & CO. request us to state that their EXHIBITION OF ANNUALS in the Royal Botanic Society's Gardens, Regent's Park, will be on view until the 12th inst.

— The subscription list in connection with the WILSON TESTIMONIAL FUND will, we are informed, be closed on the 25th inst.

Home Correspondence.

Potato Disease.—The Potato disease is once more upon us, and it will interest those who have studied the minute characters of the murrain to hear that it has broken out upon some of the Potato plants at Chiswick, just as it did in 1875, when the resting-spores of the fungus were first discovered. With this I send you a portion of one of the seed-tubers laid by Mr. Barron before the Scientific Committee of the Royal Horticultural Society on Wednesday last, and a preparation from the same tuber hastily mounted in glycerine to show the nature of the bodies visible in the corroded and gelatinous parts which are affected. If you look at my preparation (or better, make a new one from the tuber sent), and use your microscope, you will see directly that the diseased portions of the seed-tuber are traversed in every direction by innumerable threads of fine fungus spawn, and that these threads bear at their extremities the now well-known globose bodies (rich in protoplasm) originally described by me. With care you will also see the male bodies of a smaller size, some free from, others attached to, the larger. Now (as in 1875) the stems and leaves are discoloured in patches, the discoloration being clearly caused by the long continuations upwards of the threads of spawn so abundant in the seed tuber. In both stem and leaf the globose bodies are also to be found, but in these positions they are far more rare, as they were at first. If you further examine one of the Chiswick leaves, sent herewith, you will see a crop of *Peronospora infestans* just emerging from the stomata, and powdering over the brown patches. At present the aerial condition of the fungus is immature, and the conidia or spores are consequently only present in small quantities. At the present moment, therefore, we have the Potato blight upon us in its infant state. There is but one fungus now present in and upon the Potato plant, and wherever this fungus is—whether in tuber, stem, or leaf—there we also see the brown corroded patches. In each part the same cause is at work, and produces the same effect. Without doubt the storms of rain which have prevailed during the last few days have started last year's resting-spores and resting-mycelium into sudden active growth, and the murrain will speedily run on like wildfire. The destruction now certainly commenced by the fungus will not be apparent to many till two or three weeks have passed over, and then the mischief will be manifest to the least observant. If, therefore, the blight is to be attacked with any success (upon growing plants already affected) now is the only time (when the parasite is in a very young condition) that there can be any hope of success. When the *Peronospora* has secured a stronger hold, and the Potatoes are half destroyed, it will be too late to consider either prevention or cure. *W. G. Smith.*

— I am sorry to have to tell you that the Potato disease has commenced—the earliest date I have known it—in several places around here, and if it should prove virulent, it will be the worst Potato season ever known, as the tubers are so small, owing to the cold in May. I planted my Fortyfolds in the first week in March. They escaped being cut by the frost, but have made but little progress in tubering. I housed my crop, a good one, last year, in the first week in July, as I also did my Victorias, and finer or more sound Potatoes no one could wish to have. I planted all my sorts this year in March; what they will turn out to be I am afraid to imagine at present. Whilst I have the pen in hand, I may as well inform you that fruit crops in this neighbourhood are an almost total failure. For the last four years the month of May has been disastrous. *J. Scott.*

Picea religiosa.—I regret to have to state that the specimen of this graceful Conifer which I reported in the spring of 1876 as having coned here has fallen a victim to the effort. Mr. Andrew Murray gave you a full account of this rare instance of coning in your paper of April 29, 1876, accompanied by a very accurate woodcut of one of the cones, with bract, scale, seed, and leaf, executed by Mr. Worthington Smith from one of the specimens which I sent to the Horticultural Society, and which was afterwards deposited in the Museum of the Royal Botanic Gardens at Kew. I incline to attribute the death of the tree to over-coming rather than to the unfavourable season which followed. The cones had not been counted when I sent my report, and on picking them I found more than one hundred instead of forty. I had picked a very few in December, 1875, in order to secure a coloured drawing of the cones before they lost the purple tint referred to by Mr. Gordon in the notice of last spring. The cones picked in March were preserved, and the seeds which they produced were sown, (some here and some at Nichols' nursery at Redruth, but not a single plant grew, the climate of Cornwall being too cold and damp for maturing the seeds. As the parent tree is now a thing of the past I may add a few items of its history. The plant

was bought by my father in 1847, transplanted by me in 1857 into a sheltered spot in an excellent rookery. Here it died back after removal, was cut down to a promising shoot, survived the severe and deadly winter of 1860-61, lost its head again in a gale in 1867, was pruned again, and was, when it coned, a healthy though not well-shaped tree about 25 feet in height, and 2 feet 10 inches in girth at 30 inches from the ground. *John F. Rogers, Penrose, Helston, July 2.*

The Mrs. Mappin Pelargonium Sport.—I have been much interested in the reading of Messrs. Smith's explanation of the origin of the scarlet and white-flowered Pelargonium shown by them at South Kensington on the 19th ult. Understanding that it was originally a scarlet-flowered kind, I drew the attention of some friends—amongst others, of your excellent artist, Mr. W. G. Smith—to the fact that the next expanding flower had showed no evidence of white petals, and that therefore I concluded that the sport of white lower petals was only of a temporary character. The Messrs. Smith's statement that it is in reality a sport from the white-flowered Mrs. Mappin shows that I had been misinformed, and renders the character of the sport all the more interesting. That it has already produced self scarlet blooms, however, shows that not only was my estimate of the character of the opening flower-hud correct, but also that its particoloured flowers are probably things of the past. Will the originator of Mrs. Mappin tell us whether it is a genuine seedling or a sport from a scarlet-flowered variety? *A. D.*

Rève d'Or as a Climbing Rose.—I wish that all who are in doubt as to what Rose to plant (in the South of England at any rate) for covering the walls of their house could see the plant of Rève d'Or that I have at this moment in bloom. It was planted seven years ago by the wall of the east side of my vicarage; it now covers a space on that side 24 feet high by 12 broad, and has gone round to the north side, covering a space there nearly as large; the stem is 12 inches round, and from within a foot of the ground to its very outmost branches it is covered with bunches of blooms, thousands upon thousands, in all stages of development; and when I say it "covers" I use no hyperbole; there is not, on the east side at any rate (on the north it is a little thinner), a brick to be seen—unlike in this respect to the looser-habited *Solfaterre*, *Cloth of Gold*, *Gloire de Dijon*, and other climbing yellow Roses, and this after cutting out in the autumn some five or six barrowloads of wood. It is in colour very like *Madame Falcot*. The description of *Madame Falcot* would apply also to this. There has been no peculiarity of treatment, it has been allowed to run away as it liked, but its most vigorous habit has compelled me every year to thin out an immense quantity of shoots. If there be any better Rose for this purpose named I do not know it, and can most strongly recommend it as no *rève* but a reality of gold. *D. Deal.*

Oxalis corniculata rubra.—I wish to bring to the notice of your many readers the effect produced by the use of the brown-leaved *Oxalis*, which I have lately seen in the garden of Dr. Shafter, Cobham, near Exeter. Imagine a very long and wide terrace-walk, the gravel in perfect order, on either side a wide margin of grass, in equally good order; in this margin of grass on either side are planted Irish Yews, trained with the greatest care to a great height, and with a single leading stem; the number of these Yews is great, and their effect is most imposing. Between each Yew a Golden Yew is planted; at the base of each Irish Yew and around it a circle is made, it may be about 3 feet diameter, and this circle is filled with brown-leaved *Oxalis*; nothing is seen but green turf, and the circle of brown *Oxalis* which forms a base to the Irish Yews springing from it. The effect is perfect—a scene of entire harmony and repose. Much as I dislike formal gardening, with its horrible bedding-out, the perfection of taste in this terrace surprised me, and I am quite sure its finished effect was entirely caused by the use of this brown *Oxalis*, and the entire absence of all those gaudy flowers, absurd statuary and ill-shaped vases, which are the usual accompaniments of terrace decoration. Do not imagine that I object to flowers in their proper place, but the present system of bedding-out, and tying out, and torturing flowers for exhibition purposes, is opposed to all good taste. I hope some of your readers will try the brown *Oxalis*, it is evidently capable of producing the best effect. Although I have spoken very approvingly of the training of the Irish Yews in the above garden, yet I believe the principle is entirely wrong, and that a better effect would have been produced by allowing the Irish Yews to take their natural form, which is rather a full flat head, more quaint and out of the common than the cut-up single leader; but nurserymen set a fashion in training trees and the public adopt it, without due thought or consideration

whether it is right. The true rule is, let a tree, or shrub, or plant grow as Nature intended, you then have perfect form, perfect beauty. *K. K., Taddyford, Exeter.* [We cordially endorse your principles—in practice a compromise is often a necessity. EDS.]

Concerning Roses.—I have been requested to give a list of Roses suitable for culture in either of the following methods, viz., the best for general culture, the best climbing Roses.

I. THE BEST FOR GENERAL CULTURE.

I must leave out many good Roses which require a wet-nurse, a dry-nurse, and a doctor; I shall name those only that with a fair amount of attention will give satisfaction. Roses with bad constitutions and weak growth are of no use except for the exhibitor.

Baronne Prevost

Longe florent rose! Mrs. Opie (Bell) is a first-rate buttonhole Rose when just opening; Star of Waltham is a fine show Rose. I like Prince's seedling Briers* much. *W. F. Radclyffe.*

The Caper Spurge and Great Mullein.—About a fortnight since one of your correspondents asked a question about the Caper Spurge, but the tone of the remarks did not indicate that thorough appreciation of the beauty of the plant which it deserves. No wild garden should be without it; its peculiar form and colour render it a most attractive and effective plant, and there is another plant which groups well with it—the Great Mullein, *Verbascum Thaj-sus*; the large white downy leaves of the one form a fine contrast to the blue-green, angular growth of the Spurge. I have just been looking at a group of them in my garden—above twenty Mulleins, an equal number of Spurges, and about half the number of Foxgloves, in full flower, growing irregularly on a bank. No hothouse or greenhouse group of plants ever gave me more pleasure. One of the Mulleins is a grand plant; I measured the lower leaves, just 24 inches long and 9 inches wide. I expect its height when the growth is complete will be at least 6 feet. One great advantage of these plants is they give no trouble, they sow themselves, and repay with

* It is not Briers but Briers, *sic* Hebrews vi. 8. "But that which beareth thorns and briars, and is not unto cursing: whose end is to be burned." [Surely an inappropriate text this week. EDS.]

compound interest any care or attention you bestow on them. I may add that this year, from the quantity of rain and the mildness of the season during the early part of the year, I have never seen wild plants in greater perfection—a pleasant compensation for the loss of fruit. *K. K., Taddyford, Exeter.*

Phormium tenax.—I think it worth a note that *Phormium tenax* is now in flower in my garden. I am aware that it flowers in the open air in the south and west of Ireland, and in Argyleshire, but I have never before heard of its flowering in the open ground in England, except in sheltered corners in Devonshire and Cornwall, and in the Channel Islands. The flower-stem is now 7 feet high, and will be 1 foot higher, with ten or a dozen lateral flower-spikes, each containing about twenty flowers. I do not know whether this would be considered a fine specimen, but it is a very striking plant. As there is nothing exceptional either in the soil or climate of my garden I am inclined to think that the flowering of this fine liliaceous plant depends more upon age than climate. Would not the variegated forms be equally hardy? *Henry N. Ellacombe, Bilton Vicarage, near Bristol.* [At Cliveden, near Maidenhead, the variegated form seeds yearly. It is unprotected, but grows in a warm corner. EDS.]

Gorse, Furze, Whins.—In your article, p. 809, a correspondent gives a very interesting account of the Whin, *i.e.*, *Ulex europæus*, and its double variety. He has quoted Burns and Byron, as northern poets, who have just mentioned it. Burns no doubt used to see it plentifully in Ayrshire and other places south of the Grampians. I do not recollect having seen it any great distance north of Strathearn, and I have traversed many a mile in the hilly regions north of the Earn, in search of plants, and no doubt should have noticed the Whin, but I am inclined to think that it is scarcely a native, as it is so easily destroyed by severe frosts, and may, in long-past years, have travelled from some more genial clime? But this is merely supposition on my part. I am not acquainted with its geographical distribution out of Europe—that is, I am not aware that it has ever been found in any other quarter of the globe. In Great Britain it seems to be almost general south of the Grampians, at least in low latitudes, and its southernmost boundary seems to be Provence in France, where the variety called provincialis seems to take the place of our form. In Ireland they have an upright variety called, by Mackay, *U. strictus*. Besides the above we have, especially in our southern counties, the *U. nanus*, which flowers very abundantly in the autumn, covering the heaths in many parts with a close carpet of gold. The most northern point I have ever seen this sort was on the Pentland Hills. About Bournemouth it enlivens the wide spreading heaths from June till November, and to those not acquainted with the sorts it appears as if the Furze flowered all the year, for just as the *europæus* goes out of flower, the *nanus* comes in. *John Scott.*

Reports of Societies.

Royal Horticultural: July 3.—The usual afternoon meeting was held on this occasion in the large conservatory instead of in the Council-room. Lord Alfred S. Churchill, V.P., took the chair, and eleven Fellows were elected. Mr. Andrew Murray called attention to a few of the subjects exhibited, and then made some interesting comments on the Colorado Potato beetle, examples of which in various stages of development were exhibited.

SCIENTIFIC COMMITTEE.—Dr. Maxwell T. Masters, F.R.S., in the chair.

Sulphureous Earth as an Insecticide.—Mr. Murray read the following letter from Mr. Picciotto:—

"The plague of insects usually makes a greater havoc on plants in Italy than in England, and many attempts have been made to diminish the evil. Lately a friend of mine, the owner of a tract of land in the south of Italy, having found therein large deposits of a sulphureous earth containing, besides sulphur, some alkaline salts, had the idea of applying by way of experiment some of this earth to several sickly Vines and other plants. The experiment succeeded wonderfully in destroying the insects which were the cause of the malady of the plants, and restoring them to a vigour and luxuriance they never enjoyed before. The same treatment has been applied to Vines and fruit trees, to Tomatos, Roses, and various other plants and flowers with equally good success. Many independent trials have been subsequently made in different parts of Italy, and the result is a great demand for this earth.

"My friend tells me that large quantities of this earth can be supplied at a cheap rate in a condition ready for use. A large sample has been sent, and is now in London.

"As you feel interested in the subject, I shall be glad to procure you a sample of the earth, with directions for use, in case you wish to have some for experiments on a small scale. *M. H. Picciotto.*

Beetle on Cattilya Aclandiae.—Dr. Wallace sent a leaf of this plant curiously blistered by some kind of beetle, of which we shall shortly publish an illustration by Professor Westwood.

Oak Root Gall.—Mr. Murray showed specimens of this gall, which in some of its stages much resembles a Truffle, but which is the work of a Cynips, *Amphitroix radialis*.

Ustilago bromivora.—Mr. Renny showed specimens of *Bromus mollis* affected with this parasite, from a field near Kilburn, and not previously recorded as indigenous. The plants in the adjoining field were unaffected.

Lepidium Draba.—Rev. G. Henslow showed a specimen of this from the neighbourhood of London. It is supposed to have been introduced originally into the Isle of Thanet by the troops returning from the Walcheren Expedition, and has now spread over many parts of the kingdom.

New and Rare Species of Sedum.—Mr. George Maw showed specimens of Algerian and Spanish *Sedums* in bloom, on which a report will be made at some future time.

Rosa Brunonis.—Dr. Masters showed, on the part of Mr. MacIntosh, a specimen of this beautiful free-flowering white Rose.

Dr. Lindley's First Botanical Publication.—Dr. Masters called attention to a note in Lindley's own copy of his monograph of Roses in the Lindley Library, with which are bound up sundry miscellaneous notices of plants, among them a plate of *Maranta zebra*, from the *Botanical Register*, vol. v., 1819, t. 385, accompanied by a very elaborate description of the plant in question. To it is affixed the following memorandum in Dr. Lindley's handwriting:—"This was my first production in the way of botany. J. L." A similar figure and description of *Calycanthus fertilis* (t. 404) is of nearly the same date.

Pitcher on Leaf of Cabbage.—Dr. Masters showed on the part of Mr. Farquar, Fyvie Castle Gardens, a well-formed pitcher originating from the middle of the leaf of a Cabbage, together with several smaller ones. Such cases are not very uncommon. Dr. Masters made some observations as to their mode of production.

Vinegar Plant.—Mr. W. G. Smith exhibited a camera-lucida drawing of a section taken through a Vinegar Plant. The original plant grew upon lime-juice, and was one-sixteenth of an inch in thickness. As is very unusual with the Vinegar Plant the specimen in question fruited well all over the upper surface, and produced *Penicillium crustaceum*, whilst still growing in the lime-juice. No spores or conidia whatever were found in the substance of the fungus, which consisted wholly of minute septate threads matted together. Mr. Smith stated that a cubic one-sixteenth of an inch of a Vinegar Plant was traversed by no less than 550,000 distinct threads, therefore every cubic inch (a very common thickness for a Vinegar Plant) is traversed by nearly 150,000,000 of the minute mycelial filaments.

FLORAL COMMITTEE.—G. F. Wilson, Esq., in the chair. A small but by no means uninteresting collection of plants came under the notice of the committee on this occasion. H. J. Elwes, Esq., Preston House, Cirencester, again sent a splendid lot of cut flowers of various beautiful bulbous plants, including *Lilium Szovitzianum*, *philadelphicum* var. *manshuricum*, *Hensoni* var. *elegans* var. *columbianum*, *parvum*, *elegans* var. *alutaceum*, *pardalinum*, *auratum* var. *Wittei*, remarkable for its long, narrow, white petals, with a rich golden band; *Washingtonianum* var. *purpureum*, *canadense*; the charming *Calochortus splendens* and *venusta*, two pretty species of *Gladiolus* as *Colvillei* *alba*, *ringens*, *crimson*; the showy *Alstroemeria pulchella*, *Niphion junceum*, *fine golden-yellow*; *X. lustranum* var. *sordidum*, rich in purple, brown, and gold, *Brodiea congesta*, *Hyacinthus candicans*, &c. From G. F. Wilson, Esq., came fine cut spikes of the small but prettily spotted orange *Lilium columbianum*, the beautiful white *Lilium japonicum* (Kramer), and a curiously mottled variety of the same species, the small deep red *L. callosum*, the brighter coloured *L. avenaceum*, &c. Several striking Lilies were also shown by George Maw, Esq., Benthall Hall, Broseley, including *Lilium elegans* var. *Mawii*, a fine bold open flower, orange-crimson in colour and heavily spotted; and *L. croceum* var. *Chaixii*, a very distinct flower, of a bright orange-yellow colour, tinged with crimson. It was collected on the maritime Alps. First-class Certificates were awarded to both. With the above came a magnificent variety of *Lilium canadense*, collected at Haysville, Ontario; *L. canadense rubrum*, very dark; the pretty vermilion-red *L. pomponium verum*, from the maritime Alps. Mr. Maw also exhibited *Salvia interrupta*, a purplish lilac and white flower, in cultivation about seventy years ago, but subsequently lost, and again introduced by the exhibitor from Morocco. Messrs. Barr & Sugden also contributed cut spikes of a considerable number of Liliams, including about two

dozen variations of *L. Thunbergianum*, broad, open, and brightly coloured flowers, also the very showy *L. croceum splendens*, bright orange-scarlet, several well marked varieties of *L. davuricum*, and the distinct *L. monadelphum Szovitzianum*; many pretty varieties of *L. canadense*, *L. columbianum*, and the purple *Martagor*. Messrs. Barr & Sugden have also been fortunate this season in flowering a number of seedlings of the beardless *Iris Kæmpferi*, and showed to-day a dozen varieties; three of which were selected for First-class Certificates; *I. K. alba grandissima*, with magnificent white falls and standards, the falls measuring 3 inches or more across; *Robert Parker*, with rich rosy purple standards, and the fine broad falls beautifully suffused and reticulated with rosy purple—a grand variety; and *Mrs. Barr*, with pale, rosy purple standards, and broad lilac falls, very fine. Messrs. James Carter & Co. exhibited several pretty varieties of sweet Peas, and also cut blooms of two very showy *Eschscholtzias*, varieties of *E. crocea*, the one named *flora-pleno* being double, of a very bright orange-scarlet colour; and the other a single variety, named *Mandarin*, the petals of which are bright orange inside and scarlet on the exterior. Both are very showy and valuable novelties. Messrs. James Veitch & Sons received First-class Certificates for *Alocasia Thibautiana*, a very fine introduction from Borneo, the large leaves being of a dark bronzy green colour, with well-marked silvery venation; for *Rhododendron Countess of Derby*, one of the new hybrids with bright cerise flowers; for *Cypripedium albo-purpureum*, a hybrid between *C. Schlimii* and *C. Dominii*; for *Acridies crassifolia*, rose shaded with purple, very pretty. The same firm also received a Botanical Commendation for the singular little *Masdevallia triaristella* from Costa Rica, and a Second-class Certificate for *Vanda Parishii*. Messrs. J. Laing & Co. showed the new *Eulalia japonica zebrina*, in better condition than we had before seen it. From Messrs. William Paul & Son, Waltham Cross, came several new Roses, one of which, named *May Quennell*, was selected for the award of a First-class Certificate. It is a distinct and beautifully-formed flower, rosy crimson in colour, and very promising as an exhibition variety. The next most promising *H.P.* in the same stand was named *Masterpiece*, a very full rosy pink flower of excellent form. The same exhibitors also showed blooms of a charming little Moss Rose named *Little Gem*—a pink-flowered variety, in fact, of the old *Moss De Meaux*, and which certainly deserved, though it did not get, a First-class Certificate as a garden Rose. Messrs. Paul & Son, Cheshunt, also showed three new Roses, and a First-class Certificate was awarded to *H.P. Marchioness of Exeter (Laxton)*, which was put up in fine form, the rich flesh-pink of the flowers and their reflexed petals rendering them very beautiful. The other varieties were *John Bright*, a very dark crimson; and *Duke of Teck*, in the style of *Duke of Edinburgh*, from which it is a seedling, but of a brighter crimson colour, and, indeed, the nearest approach to a scarlet we have yet seen. Under the name of *Burgbley Yellow* Mr. Gilbert showed blooms of a splendid canary-yellow coloured double Rose, which was believed to be the same as the old *Double Yellow Sulphur*. Mr. Turner showed a seedling *H.P. Rose* of his own raising named *Penelope Mayo*, but very nearly resembling *Marie Baumann*, a dark rosy-crimson, and very promising. Mr. Turner also made a wonderfully effective display of cut blooms of seventy-two varieties of show *Pelargoniums*. Mr. Cannell, of Swanley, sent two fine boxes of cut blooms of *Verbenas* and *Sweet Williams*; and from Mr. Ollerhead, gr. to Sir H. Peck, M.P., came cut sprays of *Andromeda cassinefolia*, one of the most beautiful of white flowered shrubs. Messrs. Lyle & Speed, nurserymen, Cambridge, showed two seedling Ivy-leaved *Pelargoniums*, one of which, named *Bessie Speed*, a beautiful double flesh-pink flower, promises to prove a desirable acquisition. From the Society's garden, Chiswick, came a large assortment of cut blooms of *Antirrhinums* and *Sweet Williams*, the latter strain being an undoubtedly good one.

FRUIT COMMITTEE.—H. Webb, Esq., in the chair. The largest contribution made to the meeting to-day was a collection of twenty-five varieties of *Strawberries* sent up from Chiswick by Mr. Barron, and which included several of Dr. Roden's new seedlings. None of them proved to be of more than passing interest, but then this is not a Strawberry year, and more could not be expected. Messrs. Paul & Son, Cheshunt, sent samples of the Strawberry mentioned in our report of the late Crystal Palace exhibition, and which was believed by the committee to be identical with Sir Joseph Paxton. Messrs. James Veitch & Sons showed a dish of pods, and Mr. Gilbert, of Burgbley, plants of a new Pea, named *Criterion*, somewhat resembling *G. F. Wilson* or *Ne Plus Ultra*, but dwarfier than the last named, and earlier. Messrs. John Laing & Co. showed a dish of white podded Peas, under the name of *Blockburg*; and Mr. Ollerhead, gr. to Sir H. Peck, M.P., sent a couple of good Queen Pines.

The National Rose Show at St. James' Hall: July 4.—Two things were amply demonstrated on Wednesday last, on the occasion of the National Rose Society's exhibition—one, the never flagging popularity of the Rose, the other, the unsuitability of the building for the purposes to which it was devoted. It was a sight to see people who care but little for their garden in a general way, and have less feeling for their plants than they have for their cats, hovering lovingly over the long lines of parti-coloured fragrance. Ladies who we may venture to say hardly know a Cabbage from a Lettuce, a Fern from a *Ferula*, might have been seen keenly scrutinising the points of *Alfred Colomb*, dilating on the exquisite fragrance of *La France*, the deep hues of *Louis van Houtte* or *Xavier Olibo*, or the lovely tints of *François Michelin*. However, no one will care to dispute the popularity of the Rose though it may give ground for some surprise why it should, as it does, almost entirely monopolise the affections of a certain large class of the community, including no small proportion of the clergy. As to the second point, the unsuitability of the room, there can also be no doubt. Inconvenient of access and dark, the only things that could be urged in its favour were the very important considerations that no other site was available, and next, that a certain historic interest attaches to the spot, as there was held the first Rose show of a similar character, the history of which is so graphically told in the pages of *A Book about Roses*, by Reynolds Hole. Of the show itself we may say that, considering the terrible season we have had, it was undoubtedly a good one. There were about 400 entries, and over 100 exhibitors, about thirty entries being received too late, and consequently rejected. The Roses were very numerous, about 10,000 being shown, many of them as fresh as if they had not left their homes in Herefordshire, Devonshire, and other counties, and travelled through the night and the small hours of the morning to Piccadilly. Freshness, brilliancy, colour, substance, fragrance, all were there, so that he would be hard to please who could not find some gem to warm his enthusiasm and make him admit there is nothing like the Rose after all. We shall have to go into detail forthwith, but before doing so we must express our regret that nothing was done to break away from those monotonous long straight lines of colour—"all of a row"—and with scarce a variation in the level, and at the top of the tables a long row of sickly Palms, whose condition but too plainly indicated that they had been up all night. Why will rosarians strive to turn beauty into ugliness by not making the most of the loveliness Nature sets before them? A few hours' more work would be needed, but with a good plan prepared beforehand, and a good staff to carry it out, it would be possible to satisfy the requirements of the judges, the keen scrutiny of the connoisseur, and the artistic feeling of the general public. Poor public!—a roll of parti-coloured ribbon seems to be thought good enough for it.

To the general management very great praise must be given, and especially to Mr. Newman, to whom fell the lion's share of the work. The judging was quietly, systematically and speedily done, and we believe gave general satisfaction. What a contrast to the Continental system! In two hours the judges got quietly and efficiently through a mass of exhibits, many of which demanded critical nicety of judgment—a mass which would on the Continent have taken up nearly as many hours to adjudicate upon, as minutes were here required. So much for a well devised scheme systematically carried out.

THE NURSERYMEN'S CLASSES.

The whole of the six classes devoted to trade growers were of unusual excellence, the competition in each case being all that could be desired, and the blooms—well, grand. Certainly a finer lot has not been seen anywhere this season. In the leading class, which was for seventy-two distinct varieties, single trusses, the competitors were Messrs. Paul & Son, Cheshunt, Mr. B. R. Cant, Colchester, Messrs. Cranston & Co., Hereford, Mr. Keynes, Salisbury, Mr. G. Prince, Oxford, and Messrs. Davison & Co., Hereford, and as between the first few the competition was very close, it of course took some time to compare their merits and settle the order of precedence in which they should be placed, as was eventually done in the order named above as regards the first four; and Mr. George Paul is to be congratulated on his success, for he well deserved it, so grand were his blooms and so admirable his setting up. As one collection of seventy-two varieties is pretty much the same as another, we shall on this occasion, to save a repetition of names give a complete list of those staged by Messrs. Paul & Son, which were, Mons. Boncenne, *Centifolia rosea*, Mons. Noman, *Madame Ferdinand Jamin*, *La France*, Mons. E. Y. Teas, *Comte de Serenye*, *Madame C. Wood*, *Marie Finger*, *Victor Verdier*, *Peach Blossom*, *Maurice Bernardin*, *Madame Vidot*, *Duke of Edinburgh*, *Marquis de Lignereaux*, *Xavier Olibo*, *Clothilde Roland*, *Duchesse de Caylus*, *Emily*

Laxton, *Camille Bernardin*, *Catherine Mermet*, *John Bright*, *Duchesse de Vallambrosa*, *Auguste Rigaut*, *Alfred Colomb*, *Duchess of Edinburgh*, *Exposition de Brie*, *Princess Beatrice*, *Jean Souper*, *Niphotos*, *Olivier Delhomme*, *Marquis de Castellane*, *Annie Wood*, *Felix Genero*, *Mrs. Baker*, *Madame H. Jamin*, *Charles Lefebvre*, *Marchioness of Exeter*, *Lord Macaulay*, *Miss Ingram*, *Marie Baumann*, *La Ville de St. Denis*, *Jean Liabaud*, *Marguerite de St. Amand*, *Antoine Ducher*, *Abel Grand*, *Star of Waltham*, *Elic Morel*, *François Michelin*, *Ferdinand de Lesseps*, *Madame Nachury*, *Comtesse d'Oxford*, *Baroness Rothschild*, *Mrs. George Paul*, *Captain Christy*, *Etienne Levet*, *Marquis de Gibot*, *Henri Ledechaux*, *Lælia*, *Horace Vernet*, *Maréchal Niel*, *La Havre*, *Edward Morren*, *Dr. Andry*, *Marie Cointet*, *Marguerite Brassac*, *Paul Verdier*, *Louis Van Houtte*, *Madame Lacharme*, *Robert Marneck*, *La Duchesse de Morny*, and *Séateur Vaisse*. In the whole collection there was not one poor bloom, and the same may be said, indeed, of all the winning stands. In class 2, for forty-eight distinct varieties, three trusses of each, there were five competitors, and again the Cheshunt growers came in at the head of the poll, followed by Mr. Turner, Mr. Keynes, and Messrs. Cranston & Co., the unsuccessful competitors being Messrs. George Davison & Co. Here, again, were a splendid lot of blooms, and we name those shown in the 1st prize stand, most of which were also represented in the others:—*Horace Vernet*, *Madame Nachury*, *Baroness Rothschild*, *Nardy Frères*, *Marie Finger*, *La Rosière*, *Niphotos*, *Star of Waltham*, *Marguerite de St. Amand*, *Xavier Olibo*, *Madame H. Jamin*, *François Michelin*, *Marquis de Ligneris*, *Madame C. Wood*, *Madame Lacharme*, *Henri Ledechaux*, *Edward Morren*, *Charles Lefebvre*, *Maurice Bernardin*, *Catherine Mermet*, *Mrs. George Paul*, *La France*, *Etienne Levet*, *Centifolia rosea*, *Abel Grand*, *Camille Bernardin*, *Marie Baumann*, *Duchesse de Vallambrosa*, *Exposition de Brie*, *Maréchal Niel*, *Mons. E. Y. Teas*, *Victor Verdier*, *Emily Laxton*, *Marie Rady*, *Dr. Andry*, *Souvenir d'un Ami*, *Marie Cointet*, *Ferdinand de Lesseps*, *Annie Laxton*, *Alfred Colomb*, *Séateur Vaisse*, *Marchioness of Exeter*, *Devoniensis*, *Comtesse d'Oxford*, *Madame Eugénie Verdier*, *Louis Van Houtte*, *Devienne Lamy*, and *Annie Wood*. For twenty-four distinct Hybrid Perpetuals, three trusses of each, Messrs. Cranston & Co. were 1st, Messrs. Paul & Son 2d, Mr. B. R. Cant 3d, and Mr. Turner 4th. Mr. Keynes and Messrs. J. Mitchell & Sons also competed. The varieties staged in the 1st prize collection were *La France*, *Général Jacqueminot*, *Marquise de Castellane*, *Centifolia rosea*, *Monsieur Noman*, *Fisher Holmes*, *Marie Baumann*, *Marquise de Mortemart*, *Marguerite de St. Amand*, *Exposition de Brie*, *Xavier Olibo*, *Annie Laxton*, *François Michelin*, *Madame Lacharme*, *Lord Macaulay*, *Mdlle. Marie Cointet*, *Maurice Bernardin*, *Antoine Ducher*, *Baroness Rothschild*, *Beauty of Waltham*, *Baron Bonstéttin*, *Princess Beatrice*, *Duchess de Caylus*, and *Marquis de Gibot*. Messrs. Cranston & Co. again headed the prize list in the class for forty-eight single trusses, winning with a very superior lot of flowers, as indeed were those shown by Mr. B. R. Cant, Mr. Turner, and Mr. Keynes, who took the other awards; and by Messrs. J. Mitchell & Sons, Mr. G. Prince and Mr. T. Bunyard, of Ashford, Kent, the other competitors. An unusually strong competition took place in the class for twenty-four distinct single trusses, in which none of the competitors in the preceding classes could take part. The exhibitors were Messrs. Curtis, Sandford & Co., Torquay; Mr. G. Cooling, Bath; Mr. R. J. Veitch, Exeter; Messrs. J. Laing & Co., Forest Hill; Messrs. Kinmont & Kidd, Canterbury; Messrs. Robson & Bush, Beachfield, Bowdon, Cheshire; Mr. Rumsey, Waltham Cross; and Mrs. John Lewis, Thames Ditton; and the prizes were awarded to the first four in the order named above. The varieties shown in the two last mentioned classes were much about the same as those already mentioned, and therefore we need not repeat them. There were no less than seven competitors in the class for a dozen Tea or Noisette Roses, one truss of each; and here Mr. Cant came in a good list with very beautiful examples of *Devoniensis*, *Souvenir d'un Ami*, *Madame Bravy*, *Madame Caroline Kuster*, *Rubens*, *Vicomtesse de Cazes*, *Madame Willermoz*, *La Boule d'Or*, *Souvenir d'Elise*, *Catherine Mermet*, *Niphotos*, &c. Messrs. J. Mitchell & Sons were a very close 2d, Messrs. G. Davison & Co. were 3d, and Mr. Keynes was 4th—the unsuccessful exhibitors being Messrs. Paul & Son, Mr. R. J. Veitch, and Mr. G. Cooling, all of whom were capitally represented.

THE AMATEURS' CLASSES.

These were wonderfully well filled, the flowers being marked by exceeding fresh and good average quality, but suffering materially from the general dimness of light thrown upon them, and some defective arrangements of staging, inseparable from the limited space at disposal. In the class for forty-eight single trusses the premier

one open to amateurs, the first prize for which was a handsome fifty guinea challenge cup given by Messrs. Cranston & Co. of Hereford—but to be won for three years—Mr. J. Jowitt, of Hereford, was placed 1st with a singularly even and well-balanced stand, the blooms not only being of excellent quality but of good variety. The sorts were Ferdinand de Lesseps, Lord Herbert, Marquise de Castellane, Général Jacqueminot, Devoniensis, Baroness Rothschild, Duke of Edinburgh, Princess Mary of Cambridge, Dupuy Jamin, Annie Wood, Madame C. Crapet, La France, Prince Camille de Rohan, La Esmeralda, Souvenir d'un Ami, Xavier Olibo, Marie Van Houtte, Jules Margottin, Marie Cointet, Prince Arthur, Marguerite de St. Amand, Madame Marie Rady, Marie Baumann, Clement Joigneaux, François Michelin, Louis Van Houtte, Madame Nachury, Camille Bernardin, Hyppolite Jamin, Elie Morel, Captain Christy, Annie Laxton, Duchess of Edinburgh, Madame Belton, Sir Garnet Wolsley, Moonsieur Noman, Cheshunt Hybrid, Edward Morren, Louisa Ward, Maréchal Niel, Dr. Andry, Lelia, Madame Boatio, Madame Hyppolite Jamin, Exposition de Brie, Madame Marie Finger, Alfred Colomb, and a seedling, deep rose shaded violet, a very neat flower. Mr. R. N. G. Baker, of Heavitree, Exeter, was placed 2d, with a brilliant lot of blooms, somewhat less in size than the first collection, but of charming freshness. In his lot were fine flowers of Marie Baumann, Madame Victor Verdier, Captain Christy, and Alfred Colomb; 3d, the Rev. Canon Hole, of Caunton Manor, Newark, who also had a very brilliant stand of flowers, in which the novel-coloured Bernard Violet, the bright rosy pink Miller Hayes, Maréchal Vaillant, Maréchal Niel, and Baron de Bonstéttin, a deep rich crimson shaded with maroon, were exceedingly good. The Rev. J. B. Camm, of Monckton Wyld, Charmouth, was placed 4th. There were fourteen competitors. In the class for thirty-six single trusses the number of exhibitors was increased to seventeen, but the leading growers in the previous class were here again to the front, Mr. Baker taking 1st place with a stand of blooms, by no means large, but of exceeding freshness. This included Monsieur Noman, Dr. Andry, Marquise de Gibot, Sir Garnet Wolsley, Louis Van Houtte, Edward Morren, Pierre Notting, Madame Victor Verdier, La France, Etienne Levé, Ferdinand de Lesseps, Madame Charles Wood, Prince Camille de Rohan, Miss Hassard, Camille Bernardin, Marguerite de St. Amand, Lord Macaulay, Souvenir d'un Ami, Alfred Colomb, Marquise de Mortemart, Xavier Olibo, Baron de Bonstéttin, Auguste Rigotard, Countess of Oxford, Exposition de Brie, Duke of Wellington, Marquise de Castellane, Royal Standard, Baronne de Rothschild, Marie Baumann, Fisher Holmes, Mdlle. Eugénie Verdier, Charles Lefebvre, Victor Verdier, Maurice Bernardin, and Mdlle. Marie Rady. The 2d prize was taken by Mr. J. Brown, of Reigate, whose collection included good blooms of Annie Wood, Edward Morren, and Madame Levé. The Rev. E. N. Pochin, Barkby Vicarage, Leicester, was placed 3d, with flowers that were exceedingly bright, but rather overblown. His best blooms were of Charles Lefebvre, Dr. Andry, Marguerite de St. Amand, Devoniensis, and François Louvat. The Rev. Mr. Camm was 4th. In the class for eighteen single blooms the 1st prize was taken by Mr. H. Atkinson, of Brentwood, who had in excellent form Edward Morren, Charles Lefebvre, Marguerite de St. Amand, Louis Van Houtte, and Madame Clémence Joigneaux, as also were John Hopper, Marquise de Castellane, Marie Baumann, La France, Fisher Holmes, Monsieur Noman, Duke of Edinburgh, Baronne de Rothschild, Henri Ledechaux, Camille Bernardin, Duchesse d'Aoste, Duke of Wellington, Countess of Oxford, François Michelin, Anna de Diesbach, Dupuy Jamin, Dr. Andry, and Jules Margottin. Mr. Baker again took a 2d place, having charming flowers of La France, Charles Lefebvre, Mdlle. Victor Verdier, and Etienne Levé. The 3d prize was taken by Mr. Jowitt, who had fine blooms of La France, Maurice Bernardin, Mdlle. Marie Rady, and Louisa Ward. The Rev. E. N. Pochin was placed 4th. The class for twelve Roses, in threes, were placed under the gallery, and so dark was that portion of the hall that even the names were scarcely discernible. Mr. Baker was here placed 1st, with good flowers, but with deep colours rather predominating. The stand comprised Etienne Levé, Sir G. Wolsley, Xavier Olibo, Madame Victor Verdier, Camille Bernardin, Docteur Andry, Louis Van Houtte, Ferdinand de Lesseps, Charles Lefebvre, Marquise de Castellane, Marguerite de St. Amand, and Baronne (de Rothschild). Mr. J. Ridout, of Woodhatch, Reigate, was 2d, having more variety of colour, and included good flowers of Emile Hausbergh, Duc de Rohan, Mdlle. Thérèse Levé, Edward Morren; 3d, Mr. J. Scott, of Warrington; and 4th, Mr. Jowitt. The class for twelve single trusses brought twenty-seven exhibitors, and the judges had no small difficulty in awarding the prizes. Here Mr. J. J. Smallbones, of Chatteris took 1st place with Camille Bernardin, Marie Rady, Duke of Edinburgh, Abel

Grand, Etienne Levé, La France, Dupuy Jamin, Louis Van Houtte, Marquise de Castellane, Prince Camille de Rohan, Baronne de Rothschild, and Marie Baumann; 2d came Mr. Pemberton, Havering, having good Pierre Notting, Niphotos, and Edward Morren; Mr. Daniel Sewell, of St. Neots, Huntingdonshire, was placed 3d; and Mr. H. Benstead, Rochester, and the Rev. W. H. Benn, of Churchover, were equal 4th. In the class for six single trusses the prizes were taken by Mr. Laken, of Chipping-Norton, Mr. A. Evans, Oxford, Mr. Smallbones, and Mr. E. L. Fellowes, of Wimpole Rectory, Royston, in the order named. The class for a dozen Teas was also an exceedingly good one, and the awards were—1st, Mr. J. Brown, Reigate, 2d, Mr. J. Chard, 3d, Professor Adams, and 4th, Mr. W. Smith, Birch Hall, Colchester.

THE OPEN CLASSES.

In this division were classed the new Roses, and the competitions with twelve blooms each of various specified varieties, all of which were thrown open to competition, with very good results, judging by the displays made in the various classes. With a dozen new varieties not in commerce previous to 1874, the competitors were Mr. Turner, Messrs. Paul & Son, Messrs. Curtis, Sanford & Co., and Mr. Keynes, who took the four prizes in the order given; Messrs. G. Davison & Co., Messrs. Cranston & Co., and Mr. W. Rumsey. A most interesting lot of sorts was shown, but, as usual, with the exception of one or two of the leading stands, they were not in the best condition. Mr. Turner had fine blooms of Miss Hassard, Prince Arthur, a dark rich crimson; Mrs. Baker, Star of Waltham, Duchesse de Vallambrosa, Sir Garnet Wolsley, Oxonian, Madame Prosper Langier, Duke of Connaught, Royal Standard, J. Stuart Mill, and Triomphe de France. Shown in fine order by Messrs. Paul & Son, were Marchioness of Exeter, Avocat Deveriers, Madame Ferdinand Jamin, Marguerite Brassac, Comte de Serenye, La Rosière, Star of Waltham, Emily Laxton, Abel Carrière, Mons. E. Y. Teas, and Duchesse de Vallambrosa. The most noteworthy blooms in the other stands were Marshal Von Moltke, a full bright crimson; Perle des Jardins, a beautiful yellow Tea; Mons. Fournier, Star of Waltham, Amelie Hoste, a pale pink, very full, deep Rose, with a very broad petal; La Souveraine, a large, full, and well-built globular flower, of a bluish tinted pink colour, more singular and distinct than pretty. Remarkably good flowers of Alfred Colomb were shown in twelves by Messrs. Paul & Son and Messrs. J. Laing & Co., who were awarded 1st and 2d prizes respectively. No less than 7 dozen blooms of La France were staged in the class for that variety, and, for the most part, they were quite first-rate. The 1st prize lot, staged by Mr. R. W. G. Baker, were of splendid quality. Prof. Adams, the Observatory, Cambridge, was a good 2d, and Messrs. Paul and Son 3d; the other exhibitors being Mr. Turner, Messrs. Cranston & Co., Messrs. G. Davison & Co., and Mr. J. Scruby, Rundells, Harlow, Essex. The class for Maréchal Niel brought out five competitors, and the 1st prize went to a magnificent lot of blooms staged by J. H. Arkwright, Esq., Hampton Court, Leominster; the 2d to Mr. Turner, and the 3d to the Rev. W. H. Benn, Churchover Rectory. Marie Baumann was grandly shown by Mr. B. R. Cant, Messrs. Paul & Son, Mr. G. Prince, and Messrs. J. Laing, the three prizes being taken in the order named. Mr. Cant's flowers were of fine size and form, and perfect wonders on the score of freshness and brightness of colour. The splendid dark coloured Louis Van Houtte was shown by five exhibitors, and Mr. Cant again came in 1st in unexceptionable style. Mr. R. N. G. Baker was a remarkably good 2d, and Messrs. Paul & Son 3d. The class for Baroness Rothschild was perhaps the finest of all, so numerous, large and fresh were the flowers staged. Of grand size and form, and splendid as to foliage, were the 1st prize lot from Mr. R. N. G. Baker. Another very fine stand was the 2d, shown by Mr. Scruby, and the same may be said of the 3d, from Mr. Cant. Messrs. Paul & Son, and Mr. J. Ridout. Reigate, also staged flowers of great excellence. Mr. R. M. G. Baker took Messrs. Fisher Holmes & Co.'s prize for a dozen blooms of Fisher Holmes, with a nice fresh lot of blooms; and the 1st prize offered by the Rev. Canon Hole for a similar number of Reynolds Hole, was won by Messrs. Paul & Son. In the class for any variety not named above, Messrs. Curtis, Sanford & Co. came in first with a magnificent lot of François Michelin. A but slightly inferior stand of the same variety from Messrs. Paul & Son was 2d, and Mr. Turner came in 3d, with Mdlle. Cointet. For a dozen English raised seedling Roses, the names of which have been mentioned before, Messrs. Paul & Son were 1st, Mr. Turner 2d, and Mr. B. R. Cant 3d; and for three trusses of any new seedling Rose, Messrs. Paul & Son were 1st with the fine glowing crimson though rather flat John Bright, which is bright indeed; and Mr. Turner 2d, with Penelope Mayo.

Alexandra Palace: June 30.—The lessees of the Alexandra Palace were more fortunate than their Sydenham rivals in the selection of the date for holding their Rose show, though even Saturday last was, if anything, a few days too early to catch the Roses out in the greatest numbers. Though not so large a display as that made last year the present was, all things considered, an uncommonly good one, the nurserymen especially coming out strong on the point of quality, and the amateurs, as usual, with quantity, and in some instances with high quality as well. Messrs. Paul & Son, Cheshunt, took what is usually regarded as the Blue Riband of the day—i.e., the 1st prize for seventy-two single trusses; Mr. B. R. Cant, of Colchester, who was unable to show that day week, being a good 2d; Mr. John Keynes, Salisbury, 3d; and Messrs. Cranston & Co., Hereford, 4th, all showing in capital form. The Cheshunt firm also came in 1st with forty-eight trebles, Mr. Turner running them a close 2d, and Mr. Keynes 3d. In the next class, which was for twenty-four trebles of H.P.'s only, the highest award went to Mr. Cant, Mr. Turner being again placed 2d, Messrs. Paul & Son 3d, and Mr. Keynes 4th.

The Slough Roses next had a turn in the class for twenty-four singles, in which they stood well 1st, Mr. Keynes taking the 2d, Messrs. Cranston & Co. the 3d, and Mr. Cant the 4th prize. We have not attempted to name all the best blooms in each exhibitor's stands, but, to prevent a mere repetition of names, have selected for honourable mention such varieties only as were well shown in most of the stands.

THE BEST ROSES AS SHOWN.

These were François Michelin, Beauty of Waltham, Charles Lefebvre, Etienne Levé, Xavier Olibo, Prince Camille de Rohan, Marie Baumann, Centifolia rosea, Moos. E. Y. Teas, Madame C. Wood, Felix Genero, splendidly shown in most of the collections; Louis Van Houtte, very dark and rich, and of fine form; Souvenir d'Elise, Madame Lacharme, very fine in nearly every instance; Devoniensis, Mons. Etienne Levé, Maurice Bernardin, Charles Lefebvre, Mrs. George Paul, Sir Garnet Wolsley, La France, Miss Hassard, Maréchal Niel, Edward Morren, Ferdinand de Lesseps, Comtesse d'Oxford, Marguerite Brassac, Captain Christy, Emily Laxton, W. Wilson Saunders, Antoine Ducher, Cheshunt Hybrid, Miss Ingram, Baron de Bonstéttin, Exposition de Brie, Baroness Rothschild, La Rosière, Ferdinand de Lesseps, Marquise de Mortemart, Oxonian, Madame Caillat, and most of the older and better known favourites. The class for twelve Teas was a remarkably good one, and here Messrs. J. Mitchell & Sons came in 1st, with very beautiful blooms of Souvenir d'un Ami, Madame Margottin, Madame Willermoz, Jean Pernet, Souvenir d'Elise, Catherine Mermet, Marie Van Houtte, Comte Ouviaroff, Souvenir de Paul Néron, Maréchal Niel, &c. Messrs. Paul & Son were a good 2d, and Mr. Keynes 3d, an extra award being made to Mr. Turner.

AMATEURS' CLASSES.

The amateurs' classes were very strongly contested, but, as usual, with one or two notable exceptions, the blooms were a long way behind those shown in the trade classes. There were eight competitors with collections of forty-eight single blooms, the race for the premier award being very close between Mr. R. N. G. Baker, of Heavitree, Devon, and Mr. Jowitt, of Hereford, who were placed by the judges in the order named. The Rev. J. H. Gould, Mortimer, Berks, was 3d, and Mr. J. Davis, Wilton, 4th. The two first-named collections were much the best of all, Mr. Baker especially showing splendid blooms, and extraordinarily fresh, considering their long journey. Mr. Baker again came to the front with thirty-six singles, being seconded this time by Mr. Curtis, of Chatteris; the 3d prize going to Mr. Davis, Wilton; and the 4th to J. Hollingworth, Esq., Turkey Mills, Maidstone. A very good collection of twenty-four trebles won the 1st prize in the class for that number for the Rev. J. B. M. Camm, Monckton Wyld, Charmouth, Mr. R. N. G. Baker being an extremely good 2d, Mr. J. Davis 3d, and J. Hollingworth, Esq., 4th. Six collections were staged. Of five collections of twenty-four singles the best came from Mr. J. T. Smallbones, Chatteris, Mr. H. Atkinson, Brentwood, Mr. J. Mayo, Oxford, and Mr. J. Wakeley, Sittingbourne. It was the class for twelve single trusses that brought out the strongest contest. There were ten collections, and so good was the class as a whole that two extra prizes were awarded, in addition to the four offered in the schedule. The winners were Mr. J. H. Pemberton, the Round House, Havering-atte-Bower, Essex; Mr. J. Wakeley, Mr. J. Tranter, Upper Assenden, Henley-on-Thames; Mr. H. Atkinson, Mr. J. T. Smallbones, and Mr. A. Evans, Marston, near Oxford. Six collections of Teas put in an appearance, and a prize was awarded to each. Mr. J. H. Pemberton had a fine lot of blooms here too, and came in 1st again, the other awards going to the following gentlemen in the order named—Mr. C. Davis, Mr. J. Hollingworth,

Rev. J. B. M. Camm, Mr. J. W. Chard, and Mr. R. N. G. Baker.

NEW ROSES.

New Roses, though not strong in numbers, were uncommonly well shown in the classes specially devoted to them. Mr. Turner took the lead with twelve varieties sent out in 1875, 1876, or 1877, showing fine blooms of Sir Garnet Wolseley, Duchesse de Vallambrosa, Colonel de Sansal, Royal Standard, Mrs. Baker, Miss Hassard, Mons. Fournier, fine in colour, Alexander Mackenzie, Dean of Windsor, a seedling from the Duke of Edinburgh, and much in the same style, which received a Certificate of Merit; Oxonian, and the Rev. J. B. M. Camm. Messrs. Paul & Son were an excellent 2d with Star of Waltham, Emily Verdier, Miss Hassard, Madame Prosper Langier, Marguerite Brassac, Emily Laxton, Madame Ferdinand Jamin, Marchioness of Exeter, Sir Garnet Wolseley, Duchesse de Vallambrosa, Jean Liabaud and Oxonian. Mr. J. Keynes came in 3d, and Mr. G. W. Piper, Uckfield, 4th. In the class for six trusses of any Rose sent out during the same years, Messrs. Paul & Son, Cheshunt, took the premier award with beautiful blooms of Emily Laxton, and the 4th with Marchioness of Exeter. The second best was Miss Hassard, shown by Mr. Turner, and the 3d, Duchesse de Vallambrosa, staged by Mr. B. R. Cant. Messrs. Paul & Son and Mr. Turner were pretty evenly matched in the class for eighteen trusses of English raised Roses in commerce, but the Cheshunt growers had the best of the contest, coming off 1st with the following varieties:—Emily Laxton, Bessie Johnson, Cheshunt Hybrid, Miss Hassard, John Hopper, Edward Morren, Beauty of Waltham, Miss Poole, Duke of Edinburgh, Princess Mary of Cambridge, Annie Laxton, Princess Beatrice, Rev. J. B. M. Camm, Miss Ingram, Star of Waltham, Duchesse de Edinburgh, Reynolds Hole, and Marchioness of Exeter. In Mr. Turner's stand were many of the above varieties, the most notable additions to the list being Devoniansis, Marquis of Salisbury, Peach Blossom, and Lord Macaulay. The following Roses were shown in classes for twelve of each, the best coming from the exhibitors in the order named:—Duke of Edinburgh, Messrs. Paul & Son; Baroness Rothschild, Messrs. Paul & Son and Mr. Harrington, gr. to E. Mitchell, Esq., Romford; La France, Messrs. Paul & Son and Messrs. Cranston & Mayos; Marie Baumann, Mr. B. R. Cant and Mr. R. N. G. Baker; Maréchal Niel, Mr. Turner and Mr. Davies, Wilton; Princess Beatrice, Mr. B. R. Cant and Messrs. Paul & Son; Edward Morren, Messrs. Paul & Son and Messrs. Mitchell & Sons; and Madame Lacharme, Mr. B. R. Cant and Mr. Turner.

[Owing to the great pressure on our space this week, we are obliged to defer the publication of several other reports that have reached us.]

The Weather.

STATE OF THE WEATHER AT BLACKHEATH, LONDON, FOR THE WEEK ENDING WEDNESDAY, JULY 4, 1877.

MONTH AND DAY.	BAROMETER.		TEMPERATURE OF THE AIR.				WIND.	RAINFALL.			
	Mean Reading at 3 p.m.	Departure from Average of 18 years.	Highest.	Lowest.	Range.	Mean for Day.

June 28.—A very fine bright warm day. Cloudless at night.
 29.—A brilliantly fine warm day. Cloudless at night. Highest reading of thermometer in sun's rays=156°.6, being higher than any reading since July 22 1876.
 30.—A very cloudy day, a few drops of rain fell before midnight.
 July 1.—Overcast, dull, and wet till 4 P.M. Fine and bright after.
 2.—Fine but very cloudy. A shower of rain fell at 6 P.M.
 3.—A fine day, though very cloudy at times. A slight thunderstorm, with showers of rain in evening. Cloudless at night.
 4.—A bright bright day, partially cloudy. Heavy clouds in N., and a peal of thunder heard at 9 P.M. Cloudless at night.

LONDON: *Barometer.*—During the week ending Saturday, June 30, in the suburbs of London, the reading of the barometer at the level of the sea increased from 30 inches at the beginning of the week to 30.18 inches by the morning of the 25th, decreased to 30.09 inches by the evening of the 26th, increased to 30.27 inches by the morning of the 28th, and decreased to 30.13 inches by the end of the week. The mean reading for the week at sea level was 30.17 inches, being 0.23 inch above that of the preceding week, and 0.17 inch above the average.

Temperature.—The highest temperatures of the air observed by day varied from 83° on the 29th to 67° on the 24th; the mean value for the week was 73°. The lowest temperatures of the air observed by night ranged from 47° on the 25th to 55½° on the 29th; the mean value for the week was 51½°. The mean daily range of temperature in the week was 22½°, the greatest range in the day being 29½° on the 28th, and the least 16½° on the 27th.

The mean daily temperatures of the air and the departures from their respective averages were as follows:—24th, 56°.8, -3°.9; 25th, 58°.2, -2°.9; 26th, 57°.8, -3°.4; 27th, 59°.7, -1°.6; 28th, 61°.8, +0°.5; 29th, 67°.7, +6°.4; 30th, 64°.4, +2°.8. The mean temperature of the air for the week was 60°.9, being 0°.3 below the average of sixty years' observations.

The highest readings of a thermometer with blackened bulb in vacuo, placed in sun's rays, were 136½° on the 29th, 137½° on the 25th, 127½° on the 30th, and 126° on the 24th; the mean reading for the week was 131½°. The lowest readings of a thermometer on grass, with its bulb exposed to the sky, were 36½° on the 25th, 37° on the 24th, and 38½° on the 28th; the mean of the seven readings was 42°.

Wind.—The direction of the wind was W.S.W. and N.N.W., and its strength moderate. The weather during the week was very fine, bright, and dry. A very fine solar halo was seen during the afternoon of the 27th.

Rain fell on the 27th, but only to the amount of 0.03 inch.

ENGLAND: *Temperature.*—The highest temperatures of the air observed by day were 83½° at Cambridge, 83° at Blackheath, and 82½° at Norwich; at Portsmouth and Liverpool 70½° was the highest temperature in the week. The mean value from all stations was 77°. The lowest temperatures of the air observed by night were 38½° at Nottingham and 39° at Eccles; at Brighton, Portsmouth, and Liverpool 50° was the lowest temperature in the week. The general mean from all stations was 44½°. The range of temperature in the week was the greatest at Cambridge and Nottingham, both about 42°, and the least at Portsmouth and Liverpool, both 20°. The mean range of temperature from all stations was 32½°.

The mean of the seven high day temperatures was the highest at Cambridge, 74½°, and the lowest at Liverpool, 64½°; the mean value from all stations was 69½°. The mean of the seven low night temperatures was the lowest at Eccles, 47½°, and the highest at Portsmouth, 54°; the general mean from all stations was 18½°. The mean daily range of temperature in the week was the least at Liverpool, 11½°, and the greatest at Manchester, 25½°; the mean daily range from all stations was 18½°.

The mean temperature of the air for the week from all stations was 58½°, being 1½° lower than the value for the corresponding week in 1876. The highest were 61° at Blackheath, 60½° at Norwich, and 60½° at Cambridge; and the lowest were 55½° at Eccles, and 56½° at Wolverhampton.

Rain fell on six days at Bradford and Sunderland, but at southern places it fell on but one day. The amounts varied from 1 inch at Eccles and three-quarters of an inch at Manchester to one-hundredth of an inch at Truro and Plymouth. The average fall over the country was two-tenths of an inch.

The weather during the week was generally very fine and bright. A solar halo was seen at Bristol on June 27.

SCOTLAND: *Temperature.*—The highest temperatures of the air varied from 70° at Edinburgh and Dundee, to 65° at Glasgow; the mean value from all stations was 67½°. The lowest temperatures of the air ranged from 41° Dundee, to 47½° at Glasgow; the general mean from all stations was 44°. The mean range of temperature in the week was 23°.

The mean temperature of the air for the week from all stations was 56½°, being 3½° lower than the value for the corresponding week in 1876. The highest was 57½° at Glasgow, and the lowest 54½° at Aberdeen.

Rain fell at Greenock to the amount of 1½ inch; and at Aberdeen to the amount of 1½ inch; whilst at Edinburgh only one-quarter of an inch fell; the average fall over the country was three-quarters of an inch.

DUBLIN.—The highest temperature of the air was 75°, the lowest 43°, the range, 32°, the mean 60½°, and the fall of rain 0.35 inch.

JAMES GLAISHER.

Enquiries.

194. ARTIFICIAL MANURES.—*Dido* asks which artificial manure most nearly resembles cow-dung in manurial properties: will some of our chemical readers be so good as to inform him?

Answers to Correspondents.

DELPHINIUM SMITHI: *T. Smith.* Appears to be a pale blue form of *D. formosum*, which it otherwise closely resembles.

MELONS: *W. H.* The "strong" Melon plants that don't show fruit freely, and go off yellow, are probably feeding too rankly; limit the moisture at the roots for a few days, and then if they don't set stop the shoots.

NAMES OF PLANTS: *Canje.* *Cratægus Pyracantha*, propagated by budding and grafting.—*A Subscriber from the Beginning.* A variegated form of the Turkey Oak, *Q. cerris*.—*Mrs. R. 1.* *Phlomis frutescens*, yellow flower; 2, *Astrantia major*; 3, *Silene anglica*.—*W. D.* Water Starwort, *Callitriche verna*. We know no means of getting rid of it but by raking it out. It should be done at once, as the plant is in seed, though the seed is not quite ripe.—*Rambler.* The two Ferns are *Blechnum boreale*, fertile and sterile frond; the other is a moss, a species of *Hypnum*.—*K. S. Badby.* 1, *Rhinanthus crista-galli*; 2, *Valeriana officinalis*; 3, *Prunella vulgaris*; 4, *Veronica Buxbaumii*; 5, *Veronica Becabunga*; 6, *Aspidium lobatum*.—*W. M. G. 1.* *Sedum acre*; 2, *Saponaria ocymoides*; 3, *Achillea tomentosa*; 4, *Campteria bauriana*; 5, *Nephridium molle*; 6, *Diplazium Shepherdii*.—*M. J., Stoke.* *Dendrobium Wardianum*, perhaps the var. *Lowii*.—*P. H. G. 1.* *Lycaste*. It would have been better to have sent fresh specimens, as it was it was discoloured. It appears, at all events, to be *L. candida* of Dr. Lindley. It must have had green sepals, white petals and lip, and more or less purplish or light purplish spots. If this is not right, then send a copy of the sketch in colours. 2, *Cœlogyne articulata* of the younger Reichenbach; *Pholidota articulata* of Lindley. *R.* has written you fully as to the *Bletia*, that is an *Arundina* requiring further observation.—*W. H. C. Rehb.—F. Geary.* The golden sport of Birch is certainly distinct, and, if constant, is well worth propagating.—*W. H. C.* *Teucrium fruticosum*.—*J. Brown.* The yellow flower is *Kerria japonica*. The plant with numerous long-tubed red flowers is *Rochea coccinea* var. ? or perhaps a small state. The red flower with long stamens is *Clerodendron speciosissimum*.—*Mrs. Rowland.* Your plants, not numbered, are *Polygala vulgaris*, *Convolvulus soldanella*, *Veronica arvensis*, *Anthemis nobilis* (leaf only). The other looks like a small state of *Collinsia verna*, but the specimen is in bad condition.—*J. S., Cork.* 1, *Sedum Rhodiola*; 2, *Potentilla ambigua*; 3, *Potentilla procumbens*; 4, *Clematis recta*; 5, *Astragalus penduliflorus* (*Phaca alpina*); 6, *Helianthemum canum*.—*T. C. Hincks.* 1, *Oncidium pumilum*; 2, *O. uniflorum luteiflorum*; 3, *Bifrenaria aureofulva*.—*J. M. Rosa Brunonis.*

PEACHES: *J. W. C.* A bad case of black-fly. Cut off the worst shoots and wash the others with tobacco-water, Gishurst Compound, or the decoction of quassia chips so often recommended in our columns.

PETUNIAS: *R. Dean.* *P. striata* is a well-developed strain of striped varieties, very much like those of Hender's strain. *P. fimbriata* yields large and fringed flowers, mostly margined with white, often striped, and with a tendency to develope petaloid stamens; some of them are very showy. *P. grandiflorum* is a strain of very large flowers, sometimes fully 4 inches across, the predominating colour a rosy pink, but also affording striped flowers. They indicate three distinct and handsome sections of Petunias, fully up to the average as to merit. The *striata* section is the best as to intrinsic quality.

ROSES: *H. H.* We cannot undertake to name garden varieties.
 ROSE FUNGUS: *A. B.* See our Supplement. Burn the plants. 2, *Yes.*

VALLOTA: *W. H.* Let it grow on and ripen its foliage, which is evergreen, by exposure to sun and air. It will then stand through the winter in a dry greenhouse—not kept quite dry at the roots—and will flower at its natural season, about May and June. When it needs repotting do it just after flowering, as an inducement to a good development of the leaves.

VINES: *J. G. & Co.* The Vine sent shows symptoms of premature ripening, apparently caused by the use of poor soil, and by alternations of drought and moisture at the root, with perhaps an over-heated atmosphere during bursts of sunshine. There is no trace of the Vine disease.

WATERING NEWLY POTTED PLANT: *W. H.* It depends on circumstances; if the plants are not very free drinkers and the soil is fairly moist when used they may stand for a while before being watered, the time being dependent on season and weather; if they are free-growing things they may be all the better for immediate watering. More important than the actual time at which the operation is performed is the avoiding of lifting or moving them about while the soil is wet, by which it would be liable to become pudding-like, and run together too closely.

COMMUNICATIONS RECEIVED.—*D. T. F.*—*W. M. B.*—*W. E.*—*F. Holdrass*—*C. Osman*—*N. G.*—*C. R.*—*A. Young*—*Gardner*—*J. F.*—*K. K.*—*H. E. W.*—*J. C. B.*—*C. T.*—*A. W.*—*G. J.*—*A. M.*—*C. S.*—*A. F.*—*H. C.* (next week)—*A. O.*—*T. J.*—*H. S.*—*A. M.*—*E. O.*—*J. M. N.*—*W. T. D.*—*W. D.* (next week)—*R. F.*—*A. W.*—*J. V.*—*H. H. D.*—*J. O. W.*

[For Market Reports, see p. 24.]

THE IMPROVEMENT OF LANDED ESTATES,
 BY DRAINAGE, ENCLOSING, CLEARING, AND THE ERECTION OF FARM BUILDINGS AND COTTAGES.
 THE LAND LOAN AND ENFRANCHISEMENT COMPANY,
 (INCORPORATED BY SPECIAL ACT OF PARLIAMENT).

ADVANCES MONEY—

- 1st.—To the OWNERS of SETTLED and OTHER ESTATES, for the ERECTION of FARM BUILDINGS and COTTAGES, and for the DRAINAGE, IRRIGATION, ENCLOSING, CLEARING, and GENERAL IMPROVEMENT of LANDED PROPERTY, in any part of the United Kingdom.
- 2d.—To the Owners of SETTLED ESTATES in ENGLAND, for the erection or completion of MANSIONS, STABLES, and OUTBUILDINGS.
- 3d.—To Landowners generally, to enable them to subscribe for Shares in Companies, for the CONSTRUCTION of RAILWAYS and NAVIGABLE CANALS, which will beneficially affect their Estates.
- 4th.—To INCUMBENTS, for the Improvement of their GLEBE LANDS, by DRAINAGE, and the erection of FARM BUILDINGS and COTTAGES.
- 5th.—To COPYHOLDERS, for the ENFRANCHISEMENT of COPYHOLD LANDS.

The amount borrowed, with the expenses, would be charged on the Estate benefited, and repaid by a Rentcharge terminating in TWENTY-FIVE YEARS.

NO INVESTIGATION OF THE LANDOWNER'S TITLE IS NECESSARY.

Forms of Application, and all further particulars, may be obtained of Messrs. RAWLENCE & SQUAREY, 22, Great George Street, Westminster, S.W., and Salisbury; of Messrs. ASHURST, MORRIS, CRISP & Co., 6, Old Jewry, London, E.C.; of Messrs. GILLESPIE & PATERSON, W.S., 81A, George Street, Edinburgh, Agents for the Company in Scotland; and at the Offices of the Company as below.

Land, Loan, and Enfranchisement Company,
 22, Great George Street, Westminster, S.W.

T. PAIN, *Managing Director.*
 EDWIN GARRÓD, *Secretary.*

Markets.

COVENT GARDEN, July 5.

Business has been much the same as last week, with no alteration in prices. Outdoor fruit is putting in an appearance, but does not show well at present. Large quantities of Strawberries have arrived from Kent and Middlesex, and are now at their best and lowest prices. James Webber, Wholesale Apple Market.

FRUIT.

Table listing fruit prices: Apricots, per box; Cherries, per box; Grapes, per lb; Lemons, per 100; Melons, each; Oranges, per 100. Includes prices for Peaches, Pears, Pine-apples, Strawberries, and Figs.

VEGETABLES.

Table listing vegetable prices: Artichokes, English; Aubergines; Beans, French; Beet; Cabbages; Carrots; Cauliflowers; Celery; Chilis; Cucumbers; Endive; Herbs; Horse Radish; Potatoes. Includes prices for Lettuces, Mint, Mushrooms, Onions, Parsley, Peas, Radishes, Rhubarb, Salsafy, Shallots, Spinach, Garlic, Gooseberries, Turnips, and Vegetable Marrows.

CUT FLOWERS.

Table listing cut flower prices: Bouvardias; Calceolaria; Carnations; Cornflower; Eschscholtzia; Eucharis; Gardenia; Heartsease; Heliotropes; Iris; Lilies; Mignonette; Myosotis; Pelargoniums; Pink; Primula; Rocket; Roses; Spirea; Tomatoes; Stocks; Sweet Peas; Tropaeolum.

PLANTS IN POTS.

Table listing potted plant prices: Balsams; Bedding-out plants; Begonias; Bouvardias; Calceolaria; Clematis; Cockscumbs; Coleus; Cyperus; Dracena; Ferns; Ficus; Fuchsias; Heaths.

SEEDS.

LONDON: July 4.—In the absence of all consumptive sowing demand the chief interest of the seed market is now directed towards the growing crops, and the probable results thereof. As previously noted, a few samples of new French Trifolium and Sanfoin have already found their way to Mark Lane, and the prices asked have not been immoderate. Of the latter article there is a wide breadth in this country, but whether much or little of this will be saved for seed is a matter of uncertainty. Trefloils are still badly spoken of, and stocks of last year's growth are, consequently, held with increased firmness. In Clovers, unless in the execution of an occasional export order, there is nothing whatever doing. There is a small inquiry for agricultural, Rape, and Mustard seeds at unchanged currencies. In the Canary seed trade some slight improvement is observable. Blue boiling Peas have now got into very narrow compass, and fine parcels are with difficulty met with. John Shaw & Sons, Seed Merchants, 37, Mark Lane London, E.C.

CORN.

At Mark Lane on Monday the Wheat trade was quiet, and though the tone was certainly not good, no alteration was reported in prices. There was very little English Wheat offering, but the supply of foreign Wheat was large. For Barley prices were hardly so good. Malt was nominally the same, while as regards Oats last week's prices were supported. Maize was the turn cheaper, and a rather heavy market prevailed for flour. Beans and Peas were cheaper to sell.—Trade was dull on Wednesday, and any change in price was advantageous to the buyer. English Wheat was in short supply, while the imports of foreign were on a moderately extensive scale. There were remarkably few buyers, whether of Wheat, flour, Barley, Oats, or other kinds of produce, and quotations may be reported as nominally unchanged from Monday.—Average prices of

corn for the week ending June 30:—Wheat, 6s. 6d.; Barley, 3s. 11d.; Oats, 2s. 8d. For the corresponding week last year:—Wheat, 4s. 10d.; Barley, 3s. 6d.; Oats, 2s. 11d.

HAY.

At the Whitechapel Market on Tuesday, with a rather short supply trade was better, and prices firmer. Prime Clover, 100s. to 128s.; inferior, 85s. to 95s.; prime meadow hay, 90s. to 116s.; inferior, 70s. to 85s.; and straw, 44s. to 57s. per load. — On Thursday there was only a short supply of fodder on sale. There was a good trade, and prices were as follows:—Clover, best, 100s. to 132s.; inferior, 85s. to 95s.; hay, best, 90s. to 118s.; inferior, 70s. to 85s.; and straw, 44s. to 57s. per load. — Cumberland Market quotations:—Superior meadow hay, 130s. to 136s.; inferior, 105s. to 116s.; new hay, 90s. to 105s.; superior old Clover, 132s. to 140s.; inferior, 110s. to 118s.; new Clover, 90s. to 110s.; and straw, 57s. to 60s. per load.

POTATOS.

The Borough and Spitalfields Markets reports state that, with moderate arrivals, trade continues steady, the following being the quotations:—Victorias, old, 100s. to 120s.; Flukes, old, 100s. to 120s.; Rocks, 80s. to 90s.; new Jersey rounds, 240s. to 260s.; ditto kidneys, 240s. to 260s. per ton. — The Potatoes imported into London last week comprised 626 casks, 483 packages, 200 baskets, 109 bags, and 62 cases from Malta, 302 boxes, 260 cases from Cherbourg, 50 casks 25 cases from Oporto, 400 cases from Bartheur, 232 boxes from Antwerp, 153 from Lisbon, 70 cases from Bordeaux, 50 sacks from Rouen, and 19 barrels from Gibraltar.

EDGINGTON'S GARDEN NETTING

the cheapest and most durable, at 1d. per square yard, or in quantities of 250, 500, or 1000 yards, carriage free. EDGINGTON'S MARQUEES and GARDEN TENTS are the prettiest. EDGINGTON'S MARQUEES for Hire are the most handsome and capacious. EDGINGTON'S RICK CLOTHS for 71 years have maintained their celebrity as the best. HAYTHORN'S and WALLER'S NETTINGS. A quantity of good Second-hand Government TENTS from Abyssinia for Sale, Cheap. Sample of material free on application. Be particular—FREDK. EDGINGTON AND CO., 52 (only) Old Kent Road, London, S.E.

Gather Honey from Your Flowers. NEIGHBOUR'S Celebrated BEEHIVES.

PHILADELPHIA EXHIBITION, 1876. PARIS EXHIBITION, 1867. Three Silver Prize Medals awarded George Neighbour & Sons. The only English exhibitors who obtained Silver Medals for Beehives. The IMPROVED COTTAGE BEEHIVE, as originally introduced by G. Neighbour & Sons, working three bell-glasses, is neatly and strongly made of straw; it has three windows in the lower Hive. This Hive will be found to possess many practical advantages, and is more easy of management than any other Beehive that has been introduced.

Price, complete £1 15 0 Stand for ditto 0 10 6 The LIGURIAN or ITALIAN ALP BEE being much in repute, G. N. & Sons supply a Swarm of Bees with genuine Italian Queen, in the Improved Cottage Hive, at £4, Hive included. An Italian Alp Queen, with full directions for uniting to Black Stocks, 15s. each.

ENGLISH BEES.—Stocks and Swarms may be obtained as heretofore. THE APIARY. By A. NEIGHBOUR. 5s., postage 4d. A newly arranged Catalogue of other improved Hives, with Drawings and Prices, sent on receipt of two stamps. GEO. NEIGHBOUR AND SONS, 127, High Holborn, W.C., or 149, Regent Street, London, W.

THE HUNDRED GUINEA
CONSERVATORY
FIXED ANYWHERE

ART-WITH-ECONOMY-APPLIED-TO-CONSERVATORIES

In consequence of the increasing demand for Conservatories, in which pure art is combined with moderate cost, T. H. P. DENNIS & Co. have been led to introduce designs of a character hitherto unknown. One of these designs, showing a house 22 feet 6 inches x 13 feet 6 inches, is annexed, and the result, as regards the extremely low price (which includes fixing, glazing, painting, carriage, &c.), has been attained only by special machinery and a system of interchangeable parts.

T. H. P. DENNIS & Co. are also prepared to provide and fix Hot-water Heating Apparatus and Horticultural Buildings of any dimension or description.

Full sized specimens of Greenhouses, &c., and Hot-water Apparatus in work, can be inspected at Mansion House Buildings, London, E.C.

Gentlemen waited upon at their residences by experienced designers.

Estimates and Plans free.

For Sale, a
STEVENS' IMPROVED TRENTHAM
 WROUGHT IRON HORTICULTURAL BOILER,
 6 feet long by 3 feet diameter, fitted with Inlet and two Outlet
 Pipes, Fire-door and Grate complete. For price and particu-
 lars apply to
HILL AND SMITH, Brierley Hill Ironworks, Dudley.

CRITCHLEY'S PATENT
HEAT REGULATOR,
 AN APPARATUS FOR REGULATING THE HEAT
 IN HORTICULTURAL BUILDINGS.

A, Iron Box fitted up water-tight. B, Pipe or Supply of Water from Boiler. C, D, Pipes for Circulating Hot-Water. E, F, Pipes for Return of Water to Iron Box. G, Pipe for Returning Water to Boiler. H, I, J, K, Piston-Rods for Opening and Closing Valves.

The advantages of these Regulators are that houses may be kept at different degrees of heat, or the circulation of water and heat entirely stopped in one part and not in others. They may be fitted with as many valves as required, and are particularly adapted for forcing houses where top and bottom heat is used. They may be fixed in any part of the apparatus most suitable for working, without regard to the position of the Boiler.

The following Testimonial has been received:—
 "Berkeley Castle, April 13, 1875.
 "Gentlemen,—I am happy to inform you, now that the late severe winter is past, that the Hot-Water Apparatus erected by you does its work to my entire satisfaction. As to the two Heat Regulators, which represent thirty valves, I have had ample opportunities of practically proving them, and unhesitatingly admit they are far superior to any other valve; in fact, I think it the greatest improvement that has come out for horticultural purposes.
 "I am, Gentlemen, yours truly, "R. H. CRONK,
 "Gardener to the Right Hon. Lord Fitzhardinge."
 Estimates and Plans furnished for Warming Gentlemen's Mansions and Public Buildings. Orders attended to in any part of the kingdom, and guaranteed to answer their intended purposes. Prospectus and Price Lists post-free.

By Her Majesty's  Letters Patent

WRIGHT'S ENDLESS-FLAME-IMPACT HOT-WATER BOILERS.

GUARANTEED
 The most Powerful, the most Rapid, the most Economical, the Simplest, and the Cheapest in the World.

"The 'Boiler of the Future.' I have no doubt about this."—WM. THOMSON, Tweed Vineyards.

From the "Gardener," July, 1877.
WRIGHT'S PATENT ENDLESS FLAME-IMPACT BOILERS.

"The first intimation I had of the existence of these boilers, or of their inventor, was a pamphlet I received through the post. Its perusal satisfied me that Mr. Wright had a sounder theoretical knowledge of the subject of heating water than any author I had ever perused. I also liked the construction of his boiler better than any I had previously met with. Mr. Lewin, gardener, Drumeller, was represented as having fixed one of these boilers, and as bearing testimony to its excellence; and as I knew Mr. Lewin to be not only a good gardener, but a shrewd, clever man, I felt satisfied that the boiler must be of the excellence which my own knowledge of such matters led me to conclude it was from its construction.

"Having occasion to be in the neighbourhood of Glasgow last February, I went to Airdrie and called on Mr. Wright, who took me to the foundry in Glasgow where the boilers are manufactured. There he put one together in a few minutes, and a closer examination of it only strengthened my preference for it over all boilers I had previously seen. I ordered a 4-c boiler, which I have fixed to heat 2600 feet of 4-inch pipe in two early vineries. One, a Muscat-house, 200 feet long and 16 feet wide, is built and planted, the other will not be built till autumn; so that at present the boiler is only heating 1300 feet of pipe, which it does with a very small fire and the damper nearly close in, burning little more than half the coal used in any other boiler I have used—and I have seen of the most approved, both of my own and other people's designs.

"The result of the trial I have had of Wright's boiler is, that I have ordered four more, and will pull out all my other boilers as opportunity occurs, and replace them by his, with a view both of saving and efficiency.

"No doubt many will ask wherein consists the cause of the efficiency of this boiler over others? To explain this, it may be well to observe that when fresh coal is added to the fire of any other boiler known to the writer, the first process that goes on is the distillation of the gas from the new coal, and its rapid discharge, in advance of the flame, up the chimney and unconsumed. This is not only a great evil in itself, but to effect it the heat is extracted from the fire, that was in the furnace when the fresh coal was added, and little or no benefit is got from the fire till the gas is up the chimney and the destruction of the carbon in the coal has begun.

"Many expedients have been adopted to prevent this loss; and no doubt careful stoking can do much in the case of large boilers for generating steam, where there is a long fire, and where the fresh coal is always added to the front of the fire, compelling the gas to pass over the red fire and get ignited; but in the case of boilers used for heating hothouses, this is not practicable, and especially with ever-changing stokers, who, as a rule, think if they throw a given quantity of coal on the fire no further care is needed. Now, in the case of Wright's boilers, distillation of gas takes place as in others, but it has no possible chance of escape unconsumed—for gas and flame are compelled to meet face to face, over and over again, ere they leave the boiler; consequently all the gas is consumed, and the heat from it made to impinge directly on the flat surfaces of the various sections of the boiler on its way upwards. Here lies the great secret of this boiler's power.

"What also adds not a little to increase the power of the boiler is the method adopted for supplying a hot-blast, by passing air from the front of the cast-iron stand on which the boiler is placed through an intricate passage, till it is discharged at the back of the ash-pit under the bars. This leads to the most perfect combustion of the commonest cross-coal. There is also an arrangement by which a hot-blast is thrown into the furnace through the furnace door. Then there is a moderate supply of air entering the furnace all round, where the first section is laid on the heater-jacket of the boiler; this has the same effect on the fire as the well-known Argand burner has on the lamp, giving a clear fierce flame. These boilers are made up of a series of simple castings, jointed by means of india-rubber rings, which allow them to expand and contract; therefore they are sure to be the safest of boilers.

"Tweed Vineyard, June 14, 1877." WM. THOMSON.

"I think yours the most perfect 'Heat Trap' yet invented."
 —DAVID THOMSON, Driantlaunrig Gardens."

For details and particulars as to the various sizes made, and prices, please see our pamphlet, entitled, "OUR BOILERS AND HEATING," which will be handed to all applicants, post-free.

We are prepared to supply **Thirty Different Boilers** of all powers, sizes, and heights, and can vary these to suit any particular situation or requirement.

WM. WRIGHT & CO.,
 HOT-WATER ENGINEERS,
AIRDRIE, near GLASGOW, N.B.

JOSEPH BRAMHAM, HORTICULTURAL AND HOT-WATER ENGINEER, WIRE WORKER, WEAVER, &c., 104, Dale Street, and 44, Elizabeth Street, Liverpool.
 J. B. strongly recommends the **ALLERTON PRORY BOILER** as one of the most powerful for extensive work. He has fixed one capable of heating 10,000 feet of 4-inch piping. See *Gardeners' Chronicle*, p. 647. Also a **WELDED WROUGHT IRON WATERWAY BACK** for ordinary Saddle Boilers. These Backs can be fixed to any Boiler now in use, and are a great saving in fuel and labour. He is also prepared to fix any kind of Boiler made.
 Manufacturer of the Registered **LIVER FRONT** for large Boilers, **IRON and WIRE WORK** in all branches. References from Noblemen and Gentlemen for work done.
 Plans and Estimates given.

JONES'S PATENT "DOUBLE L" SADDLE BOILER.

These Boilers possess all the advantages of the old Saddle Boiler, with the following improvements—viz., the water-space at back and over top of saddle increases the heating surface to such an extent that a **PATENT DOUBLE L SADDLE BOILER** will do about twice the amount of work with the same quantity of fuel; the cost of setting is also considerably reduced, and likewise the space occupied; at the same time these Boilers are simple in construction, and being made of wrought iron are not liable to crack. They are made of the following sizes:—

Sizes.			To heat of 4-in. Pipe.	Price.
High.	Wide.	Long.	Feet.	£ s. d.
20 in.	18 "	18 "	300	7 0 0
20 "	18 "	24 "	400	8 0 0
20 "	18 "	30 "	500	9 0 0
24 "	24 "	24 "	700	12 0 0
24 "	24 "	32 "	850	14 0 0
24 "	24 "	36 "	1,000	16 0 0
24 "	24 "	48 "	1,400	20 0 0
28 "	28 "	60 "	1,800	25 0 0

Larger sizes if required.

From Mr. CHARLES YOUNG, Nurseries, Balham Hill, S.W., May 29, 1877.

"Having given your Patent 'Double L' Boilers a fair trial at my Nurseries, I beg to say that they are most satisfactory. I consider them the best in use, and without doubt the most economical of all boilers; they will burn the refuse of other tubular boilers I have in work."

PRICE LISTS of HOT-WATER PIPES and CONNECTIONS, with Boilers, of all sizes and shapes; or **ESTIMATES for HOT-WATER APPARATUS,** erected complete, will be sent on application.

J. JONES AND SONS, Iron Merchants, 6, Bankside, Southwark, London, S.E.

GREEN'S
PATENT "SILENS MESSOR,"
Or Noiseless Lawn-mowing, Rolling, and Collecting Machines for 1877.

The Winner of every Prize in all cases of competition.

The superiority of these Machines over those of all other makers is universally acknowledged. They will cut either long or short Grass, Beets, &c., wet or dry.

These advantages no other Lawn Mowers possess. They are the simplest in construction, the easiest to work, the least liable to get out of order, make little noise when in use, and are the most durable Lawn Mowers extant.

The largest stock of Mowers kept in London is to be found at our Establishment, 54 and 55, Blackfriars Road, where purchasers can select from upwards of 500 machines of hand, pony, and horse power, and have their orders executed the same day they are received.

Every Lawn Mower sent out is guaranteed to give entire satisfaction, otherwise it may be returned at once free of cost to the Purchaser.

N.B.—Those who have Lawn Mowers to repair will do well to send them either to our Leeds or London Establishment, where they will have prompt attention, as an Efficient Staff of Workmen is kept at both places.

Descriptive Illustrated Price List free on application.

Oil Paint No Longer Necessary.

HILL AND SMITH'S BLACK

VARNISH for Preserving Ironwork, Wood, or Stone. This Varnish is an excellent substitute for oil paint on all outdoor work, while it is fully two-thirds cheaper. It was introduced upwards of thirty years ago by the advertisers, and its genuine good quality, notwithstanding a host of unprincipled imitators, is fully attested by its constantly increasing sale. It may be applied by an ordinary labourer, requires no mixing or thinning, and is used cold. It is used in the grounds at Windsor Castle, Kew Gardens, and at the seats of many hundreds of the Nobility and Gentry, from whom the most flattering testimonials have been received, which HILL & SMITH will forward on application.

Sold in casks of about 30 gallons each, at 1s. 6d. per gallon, at the Manufactory, or 1s. 8d. per gallon carriage paid to any Station in the Kingdom.

UNSOLICITED TESTIMONIAL RECEIVED MAY 3, 1877.

"The Rylands, Alderly Edge, Manchester.—Messrs. Hill & Smith.—Sir,—For some 20 years I have used your 'Black Varnish,' and shall be glad if you will forward me another cask, as I consider it the best thing known for the preservation of all outdoor work, either wood or iron, that requires to be painted.

—Yours respectfully, ALFRED LOWE, J.P."

Apply to HILL and SMITH, Brierley Hill Ironworks, near Dudley; and 118, Queen Victoria Street, London, E.C., from whom only it can be obtained.

CAUTION.—It having lately come to the knowledge of HILL & SMITH that spurious imitations of this Varnish are being offered by unprincipled dealers at a slight reduction in price, they would especially draw attention to the fact that every cask of their Varnish is legibly marked with their name and address, without which none is genuine.

GRANITIC PAINT
for Sanitary Purposes.

SILICATE ZOPISSA COMPOSITION. All colours. For Damp Walls, either internal or external.

A WHOLE LIBRARY IN ITSELF.

THE ENGLISH CYCLOPÆDIA,

LARGEST, BEST, MOST COMPLETE, AND CHEAPEST.

IN TWELVE QUARTO VOLUMES, WITH A COMPLETE ATLAS OF COLOURED MAPS.

- | | |
|--|----------------|
| Durably bound in elegant cloth | Price £10 10s. |
| Also in Half-Persian Morocco | Price £12 12s. |
| And in the best Half-Russia binding, for the Library | Price £13 13s. |

The English Cyclopædia is the largest Cyclopædia.

Beyond all similar Works in the variety of its Contents, it also possesses the greatest mass of acquired information. It consists of *Fifteen Thousand* Quarto pages, with *Seven Thousand* Wood Engravings; has a complete Atlas of Maps; and contains *Sixty Thousand* separate articles and special subjects, including Biographical Memoirs and Notices. All its articles are written by those who are by their distinctive training the best qualified to describe or to give information upon their respective subjects. Its divisional arrangement is clear, distinct, and compact, bringing together in one view all the information upon each subject and branch of knowledge. Accuracy of detailed description has been attained by the employment of contributors possessed of special knowledge.

The English Cyclopædia is the cheapest Cyclopædia.

THE ENGLISH CYCLOPÆDIA contains nearly *one-fifth* more matter than is to be found in the "Encyclopædia Britannica," although it is sold at less than half the price; and exceeds, by nearly *three times*, the amount of information that is in "Chambers's Encyclopædia." The glaring deficiencies of an ENCYCLOPÆDIA aiming at a merely "popular" use are not experienced in the ENGLISH CYCLOPÆDIA. It gives exhaustiveness of detail instead of superficial sketchiness—a wider and fuller treatment of all Scientific subjects—more comprehensive views of history and its teachings—a higher appreciation of educational requirements, and an enlarged conception of the variety of miscellaneous topics, which a work intended for daily reference ought to contain.

Illustrated Prospectus, with Specimen Pages, &c., sent post-free on application.

ROYAL AGRICULTURAL SOCIETY
OF ENGLAND,
LIVERPOOL MEETING, JULY 11, 12, 13, 14, & 16.

SPECIAL DAILY EDITION

OF

THE AGRICULTURAL GAZETTE.

NOTICE.

THE PROPRIETORS of the *AGRICULTURAL GAZETTE* have arranged to Print and Publish, in the SHOWYARD, a Daily Edition of this Paper, giving a Full and Complete Report of the Liverpool Meeting.

THE DAILY EDITION

will consist of from Sixteen to Twenty-four Pages (same size as the *Agricultural Gazette*), with many Illustrations, Lists of the Prizes, &c. The price will be Twopence, and a guaranteed Daily Circulation of upwards of Five Thousand will render it a most important and valuable medium for Advertisers.

A Copy of either day's Edition will be forwarded to any part of the United Kingdom on receipt of 2½d. in postage stamps, or one Copy of each day's will be forwarded on receipt of 1s. or twelve penny postage stamps.

Application for Space for Advertisements

SHOULD BE MADE AT ONCE TO THE PUBLISHER,

A. K. BRUCE, "AGRICULTURAL GAZETTE" OFFICE,
7, CATHERINE STREET, STRAND, LONDON, W.C.

FLORAL MAGAZINE, New Series, enlarged to royal 4to; Coloured Plates and Descriptions of the choicest New Flowers for the Garden, Stove, or Conservatory. Monthly, with four beautifully Coloured Plates, 3s. 6d.

BOTANICAL MAGAZINE, Coloured Plates and Descriptions by Dr. HOOKER, C.E. Pres. R.S., of New and Rare Plants suitable for the Garden, Stove, or Greenhouse. Monthly, with six beautifully Coloured Plates, 3s. 6d.

BOTANICAL NAMES for ENGLISH READERS. By RANDALL H. ALCOCK, 6s.

"We have tested the volume in several instances, and find it very correct; and the explanations are in many instances rendered the more interesting by the fact that they are not confined to bare derivations, but indicate also the reason why the names were first applied to the plants which bear them."—Gardener's Chronicle.

"In regard to the pronunciation and meaning of plant names, it is the most reliable authority we know that is accessible to every one."—The Gardener.

"A very interesting and useful work, which may be heartily commended."—The Florist.

"This admirable work is of the greatest value, and will be widely appreciated by English readers."—Gardener's Magazine.

ADAMS and FRANCIS, Advertisement Agents, 59, Fleet Street, E.C.

Farms, Estates, Residences.

Any one desirous of Renting a Farm or Residence, or Purchasing an Estate, can have copies of the MIDLAND COUNTIES HERALD supplied free for six weeks on stating the purpose for which the paper is required, forwarding name and address, and six halfpenny stamps for postage, addressed, "Midland Counties Herald Office, Birmingham." The Midland Counties Herald always contains large numbers of advertisements relating to Farms, Estates, and Residences for Sale and to be Let.

MR. MECHE'S ADDRESS to his OLD FRIENDS and CUSTOMERS and to the PUBLIC:—

"As it has been erroneously supposed by some that I am no longer interested in my London business, I think it desirable to state that I continue to carry it on as energetically, and I trust as satisfactorily to the Public, as formerly, assisted by my only son, who will in due time succeed me. It is now fifty years ago since I first commenced business in Leadenhall Street, and what changes have taken place! Then everybody shaved, and my razor and razor-strop trade was immense; now moustache and beard are the order of the day, and the razor and strop trade is comparatively defunct. Then there were no railways, so people stayed at home and used wooden dressing-cases; now everybody travels by rail, and we have dressing-bags to suit the altered conditions. Fifty years ago the poor geese supplied our pens, and many a now rich merchant in the City will remember the quality of Mechi's shilling pen-knives; but steel pens have extinguished the pen-knife trade and the penkniving machines, and the geese are in peace, except at Michaelmas. In fact, steam has altered, and I may safely say, improved everything, and has made us a nation of travellers both by land and sea. I wonder how much time is now occupied in reading the steam-worked press? and how much less time is occupied in sipping port wine, as we used to do fifty years ago, when we could not travel? Steam will make our 4 lb loaves cheaper some day, just as it has converted calico from 2s. 6d. to 6d. or less per yard. Then, again, a letter which used to cost 6s. 6d. to Cork is now carried for 1d. Sir Rowland Hill richly deserves a monument. But to return to business: fifty years ago, when I first commenced on a small scale, I made it an axiom that what I sold should be good and useful, and I believe thousands who used the strop and paste, which I personally invented, can testify to this; it was sometimes complained of that I stamped on my razors, 'Exchanged if not approved.' I have never, and shall never so long as I live, deviate from that principle, because it is the true means to retain and increase one's connection. I devoted my attention especially to the quality and convenience of arrangements in the dressing bag and dressing case department, and in the tasteful selection of articles suitable for presentation, as well as on the matter of dispatch boxes and writing cases. Although both razors and penknives have 'gone out,' our sportsmen remain, and 'sporting knives' form one of our special departments. I feel firmly convinced that there is no fear of the departure of knives and forks, or dinners, so we make this an important department in quality and price. In conclusion, I ask no favours, but simply desire that my customers should compare the quality and price of my wares with those of other dependable establishments, and form their own conclusions. Most of my worthy assistants and workmen have been nearly forty years in my service, and long ago learned that civility and attention to our customers are as important as good quality in the articles sold. Illustrated catalogues will be forwarded post-free on application."

112, Regent Street, W., opposite Vigo Street.—1877.

ADVERTISERS are requested to note that although we do not object to receive Letters to be called for, we cannot undertake to forward them.

PARTNERSHIP.—A Nurseryman, carrying on a successful business within 25 miles of London, is desirous of meeting with a Partner. Failing health causes advertiser to wish to find a man, or men who in, say, one or two years would be able to take over from him the entire business. Money would be required, but every facility be afforded provided substantial guarantees were given. The fullest references given and required.—Address, by letter, giving outline of means and position, NURSERYMAN, Messrs. Norris, Allens & Carter, Solicitors, 20, Bedford Row, London, W.C.

WANTED, a good GARDENER, married, without family, who thoroughly understands Vines, Fruit, Flowers, &c. Wife to attend to Laundry. Wages, 30s. per week, including rooms, gas, and fringe.—Apply, stating age and full particulars, to J. M., The Grove, Elphinstone Road, Hastings.

WANTED, a married Man, as GARDENER and GROOM (one horse); must understand Greenhouses, &c. Wages 21s. per week and house found.—X. Y., Post-office, Peterborough.

WANTED, a thoroughly efficient SINGLE-HANDED GARDENER. Young married man, without family, preferred. Liberal wages, and cottage found.—T. BROWN, Esq., Longfield, Headingley, Leeds, Yorkshire.

WANTED, a good WORKING GARDENER; must be well up in all branches of the profession, and have an interest and pushing in his work that thorough confidence can be placed in, as he will have to take entire charge of the place six months in the year. Wages according to ability. First-class character required from last employer.—J. C., Mr. Cass, Prospect Street, Hull.

Under Gardener.

WANTED, for a Gentleman's family, a married Man, without family. Wife to keep the Lodge. Age about 30.—Address, stating wages and previous service, M. T., Horton Manor, Epsom.

WANTED, a First-class FOREMAN and PROPAGATOR, In and Outdoor; must be a good Salesman; he must thoroughly understand the Propagation of Roses, Conifers, Rhododendrons, Fruit Trees, and all kinds of Forest Trees and Shrubs usually grown in a Nursery; also be thoroughly steady and industrious. State experience, and where last lived or living, and wages expected.—WITTY AND SON, Cotingham, near Hull.

WANTED, as GENERAL NURSERY FOREMAN, an energetic and steady Man, to take Management under master. Must be a good Budder and Grafter, and well versed in all departments. Also, at once, **ONE or TWO expert BUDDERS.**—State wages, references, &c., to **GEORGE COOLING,** Nurseryman, Bath.

WANTED as GROWER and PROPAGATOR of Roses, Rhododendrons, Ornamental Trees and Shrubs, an active, intelligent, and sober Man, able to act as Salesman when needed.—Apply, with full particulars, to **R. P. KER AND SON,** Aigburth Nursery, Liverpool.

WANTED, a thoroughly reliable Man—an expert BUDDER and GRAFTER—with a good knowledge of General Nursery Work (Outdoor). Wages, 22s. per week. Also a steady MAN, used to General Nursery Work, able to assist in Painting and Glazing, and make himself generally useful. Wages, 20s. per week. Also a good **JOBBING HAND.** Wages, 20s. per week. State age and reference.—**GEORGE J. WOOLLETT,** Nurseries, Caterham, Surrey.

To Rose Budders.

WANTED, for a short time, an expert ROSE BUDDER.—Address, stating terms, to **GEORGE BOLTON,** Wyddial, Buntingford, Herts.

North of England Rose Nurseries,
Catterick Bridge, Yorkshire.

MANAGER.—The Executors of the late Mr. John Harrison require the services of a competent Manager to take entire Charge of the Nurseries, consisting of about 50 acres. A suitable person will be liberally treated with. They also require the services of a good **CLERK** and **BOOK-KEEPER.**—Apply, with full name and address, and giving references, also stating salary expected, to **WM. HARRISON,** South Grove, Rotherham.

WANTED, a steady Young MAN, to attend to the Fires; one that can Paint and Glaze preferred.—Apply, with full particulars, to **JOHN WILLS,** Royal Exotic Nursery, Onslow Crescent, South Kensington, S.W.

WANTED, IMMEDIATELY, an active, industrious young MAN, from 18 to 20 years of age, to assist in the Houses.—Apply, by letter, stating wages required, &c., to **Mr. WILLIAM BARNES,** The Garden, Searles, near Uckfield, Sussex.

Clerk

WANTED in a London Seed Warehouse, a Managing and Confidential **CLERK** and **TRAVELLER.**—Unexceptionable references as to character and ability required.—State amount of experience, and all particulars, to **C. D.,** *Gardeners' Chronicle* Office, W.C.

Seed Trade.

WANTED, an intelligent, respectable young MAN, with some experience, in a small Retail Shop, and to make out Invoices, &c.—State age, reference, and wages, to **JAMES BIRD,** Nurseryman, Downham.

WANTED, a Young MAN, with two or three years' experience, to Assist in the Seed Shop.—Apply, stating wages required, and where last employed, to **W. J. WATSON,** Town Hall Buildings, Newcastle-on-Tyne.

WANT PLACES.

B. S. WILLIAMS, having at the present time several very excellent **GARDENERS** upon his Register, is desirous of placing them in Situations where great experience and trust are required. **B. S. W.** would at the same time beg to intimate that when a Gardener is applied for that the filling of the situation should be left with him, as that would prevent unnecessary correspondence and delay.—Victoria and Paradise Nurseries, Upper Holloway, London, N.

Head Gardeners.

JOHN LAING AND CO. can at present recommend with every confidence several energetic and practical Men, of tested ability and first-rate character. Ladies and Gentlemen in WANT of **GARDENERS** and **BAILIFFS,** or **GARDENERS** for First-rate Establishments or Single-hand Situations, can be suited, and have full particulars by applying at Stanstead Park and Rutland Park Nurseries, Forest Hill, London, S.E.

E. G. HENDERSON AND SON have many excellent **GARDENERS** with approved testimonials for ability now waiting in their Nurseries for re-engagement.

E. G. H. & Son will be pleased to answer any enquiries from Noblemen and Gentlemen requiring such.—Pine-apple Nursery, Maida Vale, London, W.

GARDENER (HEAD).—Has a thorough knowledge of Stove and Greenhouse Plants, Pines, and Orchids, all kinds of Forcing, Kitchen Gardening, and Laying-out Grounds.—**A. H.,** 25, Bradford Road, Sydenham, S.E.

GARDENER (HEAD).—Age 33, married; thorough practical knowledge of all branches. Good character.—**W. ALLISTON,** Tenth Milestone Cottage, Staines Road, Hounslow, W.

GARDENER (HEAD).—Age 25, single; steady, energetic, proficient in the Cultivation of Vines, Peaches, Kitchen Gardening, and general routine of Gardening. Head Gardener four years.—**C. TAGGETT,** Ashley Down, near Bristol.

GARDENER (HEAD), age 37, married.—**J. WOODFIELD,** for the past eleven years Head Gardener to **F. J. S. Fojfjambe, Esq., M.P.,** Osberton, offers his services to any Noblemen or Gentlemen requiring a thorough practical Gardener.—**Osberton Gardens, Worksop, Notts.**

GARDENER (HEAD).—Age 39, married; thoroughly understands the profession in all its branches; nineteen years' experience in large Establishments. 11 years' good character from late employer.—**T. STEVENS,** 11, Warren Road, Reigate.

GARDENER (HEAD).—Single; thoroughly practical in all branches of the profession, including Orchids and Pines. Stock if required. Ten years' good character.—**G. WATERMAN,** The Gardens, Crux, Hatfield Feveler, Chelmsford.

GARDENER (HEAD).—Age 41, married, no family; understands the routine of garden work generally. Twenty years' experience in large gardens—four years in present situation, eleven and a-half years previous. Good character from present and past employers.—**W. PAYNE,** Ford Manor, Lingfield, Surrey.

GARDENER (HEAD).—Age 39, married, without encumbrance; thoroughly understands the profession in all its branches. Wife can attend to House during absence of family. Leaving his present employment owing to the breaking up of the establishment. Can have unexceptionable character for last three and a-half years. Suburbs of London preferred.—**J. C.,** Guisnes Court, Kelvedon, Essex.

GARDENER (HEAD, WORKING), where one or more are kept.—Married, one child; thoroughly practical in all branches.—**G. L. S.,** Rymer Street, Herne Hill, London, S.E.

GARDENER (HEAD, WORKING, or good SINGLE-HANDED).—Age 27, single at present. Six and a-half years' excellent character.—Address, with all particulars, to **A. T., F. Attwood's,** Nonington, Wingham, Kent.

GARDENER (HEAD, WORKING).—Age 32, married, no family; thoroughly understands the profession. No single-handed place accepted. Satisfactory references.—**A. M.,** Cockley Cley Hall, Swaffham, Norfolk.

GARDENER (HEAD, WORKING).—**H. NOTT,** Eashing Park, Godalming, wishes to treat with any Lady or Gentleman requiring a thorough practical Man as above. First-rate character.

GARDENER (HEAD, WORKING).—Age 40, married, no encumbrance; understands Vines, Stove and Greenhouse Plants, and Flower and Kitchen Gardening. Wife could Manage Dairy. Eleven years' good character.—**W.,** 1, Alma Cottages, Leigham Lane, Streatham.

To Noblemen and Gentlemen.

GARDENER (HEAD, WORKING).—Age 29, married, one child; has had much practical experience in the cultivation of all kinds of Plants, Fruits, and Vegetables; well up in Modern Flower Gardening, Dissectable Decoration, and the Laying-out of New Grounds. Is sober, energetic, and well recommended.—**WILLIAM PLUMB,** The Lodge, Regent's Park College, London, N.W.

GARDENER (HEAD, WORKING, SINGLE-HANDED, or otherwise).—Age 28, no family; thoroughly practical. Wife understands Dairy and Poultry if required. Good character.—**A. C.,** The Library, Elgin Road, Maida Vale, London, W.

GARDENER (HEAD or good SINGLE-HANDED).—Married; understands Vines, Cucumbers, and Melons, Forcing Peaches and Nectarines, Flower and Kitchen Gardening. Six and a-half years' good character.—**J. WHITBREAD,** Lindsey Street, Epping, Essex.

GARDENER, where one or more are kept.—Good testimonials from late and present employer.—**S. H.,** 30, Stamford Road, Standley Bridge, Fulham, S.W.

GARDENER, where two or more are kept.—Age 24, single; nine years' experience in all branches of the profession. Good character.—**JOHN BRAITHWAITE,** The Farm, Acomb, near York.

GARDENER.—Age 30, married; to take Charge of Pleasure and Kitchen Garden, Greenhouse, &c.; can look after a Horse and Carriage. Country preferred. Can be highly recommended by **E. MALLER,** Nurseryman, Lewisham, S.E.

GARDENER (SECOND), where three or four are kept.—Thirteen months' good character. Bothy preferred. Total abstainer.—**A. H.,** Gaddesden Park, Hemel Hempstead, Herts.

GARDENER (SECOND), in the Houses, where three or four are kept.—Six years' good character. **C. DUNHAM,** The Gardens, West Park, near Amphil, Bedfordshire.

GARDENER (UNDER).—Used to Vines, Pines, and Plants. Indoors preferred. Good character.—**H. E. PICKNELL,** Advertising Agent, Cuckfield, Sussex.

GARDENER (UNDER), in a good Establishment.—Age 20; good character.—**M. N.,** Post-office, Highbury, London, N.

GARDENER (UNDER), in a good Establishment.—Good character.—**B. SAVAGE,** Lade Bank, Leake, near Boston.

GARDENER and STEWARD.—Age 26; holds First-class Certificates from the best gardens in Great Britain, Horticultural and Botanical, and a First-class Certificate from the Technological Society on Agriculture; has been in present place four years, where he has had the Management of many men in various improvements, and, wishing to promote himself, is ready for an engagement as Gardener and Steward, or in either capacity in a good place.—Address to advertiser, **JOHN BRENNAN,** Manor Gardens, Loughgall, County Armagh.

GARDENER (UNDER), or JOURNEYMAN, under Glass, in a good Establishment.—Age 20. Good character from last place.—**T. B. A.,** Post-office, Trentham, near Stoke-on-Trent, Staffordshire.

FOREMAN, or SINGLE-HANDED where assistance is given.—Thoroughly experienced in all Exotic Plants, Fruit, &c.—**H. L.,** Grove Terrace, Beverley.

FOREMAN, in a Nobleman's or Gentleman's Establishment.—Age 25; ten years' experience in first-class places. Highly recommended.—**D. B.,** Eynsford, Dartford, Kent.

FOREMAN, in a large Private Establishment, where Forcing is extensively carried on.—Age 25. First-rate character.—Apply to present employer, **C. W. WILSHERE,** The Frythe, Welwyn.

FOREMAN, in the Houses, in a good Establishment.—Age 25; nine years' experience.—Good character.—**T. B.,** Post-office, Highbury, London, N.

FOREMAN and PROPAGATOR in a Nursery.—Age 28. Please state wages, &c., to **R. G.,** Post-office, Cotham, Bristol.

FOREMAN, or PROPAGATOR.—Well-up in Roses, Fruit Trees, Rhododendrons, Clematis, Conifers, &c. Good references.—**S. L.,** Messrs. Pengelly & Pool, Nurserymen and Seedsmen, &c., 59, Queen Victoria Street, London, E.C.

To Nurserymen.

MANAGER, GENERAL FOREMAN, or in Glass Department.—Well acquainted with all branches of the profession. First-rate references.—**J. J.,** Post-office, Forest Hill, S.E.

JOURNEYMAN, in a good Establishment.—Age 20; willing. Good reference.—**Mr. HORWOOD,** Keyfield Nursery, St. Albans, Herts.

JOURNEYMAN, in a Nobleman's or Gentleman's Garden.—Age 23. Good character.—**G. C. H.,** 36, Cochrane Street, St. John's Wood, London, N.W.

JOURNEYMAN, in a Large Establishment.—**THOMAS PRITCHARD** can with confidence recommend **H. Wells** to any Gardener who may be in want of a thoroughly industrious and steady young Man (age 24). Near London preferred.—**Umberslade Gardens, Hockley Heath, Birmingham.**

PROPAGATOR.—**Mr. WILLIAM BULL** is in want of a thoroughly efficient Propagator. None need apply whose character will not bear the strictest investigation. Application to be made personally.—Establishment for New and Rare Plants, King's Road, Chelsea, London, S.W.

IMPROVER, in a good Market Nursery.—Propagating-houses preferred.—Age 20; good trade experience.—**J. F.,** Post-office, Crown Terrace, Upper Holloway, N.

IMPROVER, in the Houses, in a Gentleman's Garden.—Age 18. Two years in present situation.—**A. D.,** The Gardens, Mottisfont Abbey, Near Romsey, Hants

IMPROVER, in a Gentleman's Garden.—Age 19; steady, well educated; has had three years' experience in Houses and Gardens. Good references.—**Y. Z.,** Mrs. House, Evendon, Wokingham, Berks.

New South Wales or New Zealand.

TO MERCHANTS, ACCOUNTANTS, AGRICULTURISTS, and OTHERS.—A young Man (age 25) leaving for the Colonies is desirous of obtaining an engagement. Good knowledge of Corn, Seeds, and Plants, and also of Book-keeping. First-class character and references.—**COLONIAL, Albert Cottage, Clifton View, Bedminster, Bristol.**

TO NURSERYMEN, &c.—As Leading Man in Jobbing Work.—First-class Workman. Also a useful handy man as Plain Carpenter, Glazier, Painter, Pipe-Fitter, &c., in a good Establishment, near London.—State wages and particulars to **G. & C.,** Post-office, Upper Sunbury, Middlesex.

MANAGER, BOOK-KEEPER, or CLERK, in a Nursery, Seed, or Florist Business.—Age 32. First-class references.—**K. W.,** 2, Burrell Street, Ipswich.

To the Seed Trade.

SHOPMAN (ASSISTANT).—Four years' experience. Good reference. Security given.—**T. H.,** 29, Quay, Waterford.

SHOPMAN.—Age 25; ten years' experience in London and the Provinces. Will be disengaged in six weeks.—**N. R.,** *Gardeners' Chronicle* Office, W.C.

CARPENTERS, on a Gentleman's Estate.—Two young Men seek situations as above; can do General Repairs, also Horticultural Work in every branch.—Apply, by letter, to **R. W. F.,** 9, Grove Lane, Stamford Hill, London, N.

KINAHAN'S LL WHISKY.

Kinahan & Co., finding that, through the recommendation of the Medical Profession, the demand for their **CELEBRATED OLD LL WHISKY** for purely medicinal purposes is very great, submit with pleasure the following Analysis by **Dr. Hassall**:—"I have very carefully and fully analysed samples of this well-known and popular Whisky. The samples were soft and mellow to the taste, aromatic and ethereal to the smell. The Whisky must be pronounced to be pure, well-matured, and of very excellent quality. The Medical Profession may feel full confidence in the purity and quality of this Whisky."—**20, Great Titchfield Street, Oxford Street, London, W.**

DINNEFORD'S FLUID MAGNESIA.

The best remedy for **ACIDITY of the STOMACH, HEARTBURN, HEADACHE, GOUT, and INDIGESTION;** and the safest aperient for delicate Constitutions, Ladies, Children, and Infants.—**DINNEFORD AND CO.,** 172, New Bond Street, London, and all Chemists.

HOLLOWAY'S PILLS.

Nervous Debility.—No part of the human machine requires more watching than the nervous system—upon it hangs health and life itself. These Pills are the best regulators and strengtheners of the nerves, and the safest general purifiers. Nausea, headache, giddiness, numbness, and mental apathy yield to them. They dispart in a summary manner those distressing dyspeptic symptoms, stomachic pains, fulness at the pit of the stomach, abdominal distension, and overcome both capricious appetites and confined bowels—the commonly accompanying signs of defective or deranged nervous power. Holloway's Pills are particularly recommended to persons of studious and sedentary habits, who gradually sink into a nervous and debilitated state, unless some such restorative be occasionally taken.

J. WEEKS & CO.'S ADDRESS

To the Nobility, Gentry, and their Friends.

ENCOURAGED by the support hitherto accorded us, we beg to announce that we are now issuing a new and beautifully Illustrated Catalogue of Ornamental Conservatories, which we confidently hope will satisfy the advanced and somewhat fastidious taste of the present age. It is now upwards of fifty years since our business was first established, and in that time what improvements in the tastes and habits of the nation have taken place! Then four brick walls with holes in them at intervals, without any attempt at ornament, met the views of the wealthy Englishman with regard to the external appearance of his dwelling; now he builds for himself a mansion of imposing or picturesque elevation, enriched with costly marbles and adorned with choicest specimens of the sculptor's art. Then the common objects of household use were badly finished, often ill-adapted to their purpose and generally ugly; now perfection is the goal aimed at, and beauty and utility go hand in hand. Then Conservatories were simply regarded as places to shelter plants, and were with a few exceptions very commonplace structures; now the fact that appropriate architectural accessories greatly enhance the effect of flowers and plants is universally admitted, and the erection of elegant and costly buildings is the result. If it be true, as some one has said, that the character of an individual is best known by his pleasures, how great an elevation has the character of the nation undergone within that period, and how greatly has horticulture benefited by the change! Then the national pleasures were mostly inelegant and often coarse; now they are much more refined. Then Horticulture was regarded as a science very well for professional gardeners, and but rarely practised by amateurs; now it has become a popular and fashionable recreation. Then a Conservatory was the exception, and was usually a glasshouse of unornamental character at some distance from the mansion, seldom visited by the family; now a conservatory is considered necessary for every house of any pretensions, and is attached to, greatly adorns, nay, frequently forms the most costly part of it—the chosen rendezvous of the family and its guests, the cool and leafy retreat from the ball-room and the most enjoyable after-dinner lounge.

Then, again, the improvements in the appliances for Warming Horticultural Structures have kept pace with the improvements in their artistic embellishment. When our business was first established, the old hot-air flue was in vogue, the science of heating by hot water was comparatively unknown, and the system employed most primitive—each house being warmed by a separate boiler, thus causing an immense amount of labour and serious waste of fuel. The whole aspect of affairs, however, was completely altered by the introduction in 1848 of our "Weeks's Patent Upright Tubular Boiler," which is pronounced by eminent engineers to be "the" Boiler for heating by hot water, being superior in rapidity and power to any other, thus enabling whole Horticultural Establishments to be heated from one stokehole by one furnace. Not content with this success, but bent on making a perfect Boiler, we have expended large sums in carrying out experiments on an extensive scale, and from time to time have effected various improvements, which render our "Weeks's Patent Upright Tubular Duplex Boiler" with Patent Fuel Economiser unequalled. Upwards of 3000 of our Boilers are now in operation in various parts of the United Kingdom, heating Horticultural Establishments, Conservatories, Mansions, Public Offices and Institutions, Cathedrals, Churches, Manufactories, Banks, Prisons, Baths, Hospitals, Zoological Gardens, &c.—in some instances as much as 3 miles of piping being warmed from one stokehole. In conclusion we beg to state that we still adhere to our old principle that "the best is the cheapest in the end." All buildings erected by us are manufactured by skilled workmen from the best materials. Every Hot-water Apparatus is warranted to answer its intended purpose, and every "Duplex Boiler" fixed by us is guaranteed for ten years. Catalogues free on application to

ADDRESS.

SUPPLEMENT TO THE GARDENERS' CHRONICLE.

THE ROSE.

SCIENCE, poetry, and legendary lore have for centuries been engaged searching out, sentimentalising and imagining the history of the Rose. It would require a bulky volume to contain all the facts known regarding the Queen of Flowers, while fable is always busy inventing fresh wonders regarding this beautiful plant. The Rose is not the favourite of an age, but of all time—not the special growth of one little spot of earth, but dispersed over the known world. Familiar to the ancient Egyptians, mentioned in the Book of Wisdom, and sung by Anacreon in his *Odes*, the Rose has held its own against all flowers since the time when written chronicles were first known.

Among the poetical origins assigned to the Rose that of Anacreon is one of the best known—

“When Cythera, naked to the light,
Waked from her Neptunian birth
To fill with love the circling earth,
Then—then, in strange eventful hour,
The earth produced an infant flower,
By chance, upon a blooming Thorn.
Some nectar drops in ruby tide
Its sweetly Orient buds had dyed:
The gods beheld the brilliant birth,
And hail'd the Rose—the boon of earth:
They bade them bloom, the flowers divine
Of him who shed the teeming Vine,
And bade them on the spangled Thorn
Expose their bosoms to the morn.”

Yet, although written in prose, that concerning Rhodanthe is scarcely less

poetical, for, as the legend runs, “several princes were enamoured with Rhodanthe, a beautiful Queen of Corinth. She, however, rejecting all of them, in the blind fury of disdained love took refuge in a temple of Diana. Her subjects, who defended her, dazzled by her extraordinary beauty, made her assume the place of the statue of the goddess. Apollo, enraged by this indignity to his sister, changed Rhodanthe into the first Rose tree, her subjects into the thorns, and the three princes into butterflies, which still continue to flutter round their cherished love.”

But it is not the Rose itself only which has engaged the attention of the poet. Roses are red as well as white, and to account for the former it is said that, originally white, the flower was stained with the blood of Venus, whose feet were lacerated by the thorns when she was endeavouring to rescue Adonis. Spencer alludes to the incident in the following couplet:—

“White as the native Rose, before the change
Which Venus' blood did in her leaves impress.”

Then, too, we have to account not only for the colour but also the scent of this peerless flower—

“Dear to earth its smiling bloom,
Dear to heaven its rich perfume.”

—a perfume which, we may imagine, was left by the breath of Venus, or imparted to it by some love-lorn maid. This idea is suggested in the following lines by Ben Jonson:—

“I sent thee late a rosy wreath,
Not so much honouring thee
As giving it a hope that there
It could not withered be.

“But thou thereon didst only breathe,
And sent'st it back to me;
Since when it grows and smells, I swear,
Not of itself, but thee.”

But beauty, bloom, and scent do not exhaust the list of qualifications which have raised the Rose to the highest pinnacle of floral fame. Other flowers are, beyond doubt, beautiful, brilliant, and sweetly odorous; but what other has a variety which is enveloped in a delicate nest of moss? In this surely is the Rose unique; and to what strange accident is so charming an addition to the most charming of flowers due? Perhaps some other of Flora's favourites, envious of the beauty of the Rose, enveloped it in moss, in the hope of hiding its charms; but the moss, like modesty in a fair maid, only enhances the beauty it is meant to hide.

The likening of children to Rose-buds, and young girls to the opening flowers, has become so hackneyed in poetic usage that the simile is sufficient to render ridiculous otherwise good verse, but we know of only one instance where a youth is compared to a Rose. It occurs in *Hamlet*, where Ophelia terms the Prince of Denmark

“The expectancy and Rose of this fair state.”

But this universal flower is not alone the ideal of poets and the beloved of gods and goddesses—it is entwined with the veritable history of nations, as exemplified in the chronicles of our country, a long epoch of national calamities and civil strife being known as the Wars of the Roses.

The Red Rose of Lancaster, which occupies so prominent a position in English history, was assumed as

a badge by Count Egmond, son of Henry III., and founder of the House of Lancaster. About 1277 Guillaume Pentecote, Mayor of Provins, having been assassinated in a tumult, the King of France sent Count Egmond to avenge his death. After restoring order the King conferred on him the title of Comte de Champagne, and he then took for his device the Rose, which Thibaut, Comte de Brie and Champagne, had brought from the East, on his return from the Holy War. Consequently, the botanists tell messieurs the heralds and historians that the Rose of Lancaster was a damask (dark crimson) and not a red Rose. The white Rose was most probably assumed by the Yorkists in contradistinction, for the Plantagenet badge was a slip of Broom.

Plantagenet. “Since you are tongue-ty'd and so loth to speak,

In dumb significance proclaim your thoughts;
Let him that is a true-born gentleman,
And stands upon the honour of his birth,
If he suppose that I have pleaded truth
From off this Brier pluck a white Rose with me.”

Then the Lancastrians plucked each a red Rose, and Warwick truly prophesied—

“This brawl to-day
Grown to this faction, in the Temple Garden,
Shall send, between the red Rose and the white,
A thousand souls to death and deadly night,”

—a quarrel which only ended when the red Rose and the white were twined together by the intermarriage of the houses of York and Lancaster, at which time, it is said, a florist made a fortune with the happy combination of the two colours by hybridising the plants—the result being a streaked Rose, which was called the York-and-Lancaster, or the Union. Within the last few years these Roses were still quite common in farmhouse and cottage gardens in Lancashire, though but few of the possessors of this relic of historical interest appeared to have any idea of the origin of the combined colours.

The Rose is still one of our national emblems, but other countries also hold it in high esteem. The gift of a golden Rose, consecrated by the Pope, and presented by him to a crowned head, is the greatest honour it is possible for a Roman Catholic to receive. Such a distinction has been twice conferred, we believe, in our time. One was sent to the ex-Queen of Spain, and one to the ex-Empress of the French. Strangely enough the Rose, also, was the device on the seal of the great Protestant reformer, Luther.

English nurserymen catalogue over 2000 varieties of the Rose, but among them, we imagine, would be found many with a distinction without a difference. The different varieties of Roses, however, are quite numerous enough to justify the boast of a successful cultivator that he had a different Rose for his button-hole every day in the year, for the Rose is found in one or other of its varieties in almost every part of the known world. It blooms beneath the scorching sun of the tropics, and cheers the short-lived Arctic summer with its pale roseate flowers, appearing like an emanation of the red-tinted snow which has for so many months covered the ground. ♀

ROSE CULTURE.

I AM not going to write a lengthened essay on Rose culture, but just to give a few useful and practical suggestions. There are plenty of existing books on the Rose, representing every branch of culture, but who can write of seasons before they come? or who can write of evils, or suggest remedies to be of any practical use, before the former are apparent, espe-

cially if they are climatal? Well, Lancashire does not bear the best of names for a good climate, and I cannot take up the cudgels for her; she tries patience very often in that respect, and has maintained her reputation in 1877. The greatest difficulty we labour under here is "climate;" people can say what they will, talk for a century if they like, but those who do not succeed in growing grand Roses may sum up the reason in three words—"soil and climate," especially the latter; next comes situation.

If you want to be a good customer to nurserymen, and to buy Roses every year, purchase your stock from a good climate and plant them over as wide an area as you can when they reach home—plant on shrubby banks and borders, where they will be half-starved or roasted during a hot or dry summer or worried with green-fly or other aphids to which the Rose is subject when grown in unfavourable situations and well neglected. If on the other hand you desire to succeed, purchase your Roses from some grower contiguous to home, or at all events from a worse climate than your own if possible; have your mind made up that they shall have your earliest and best attention, which means careful planting when the soil (which must be as good as can be obtained) is in a favourable state for the operation of planting to be performed. Try if possible to select a plot of ground well sheltered from cutting winds; and herein lies the greatest secret in Rose growing in this variable Lancashire climate of ours. I have seen cases where no expense has been spared in preparation fail, when others with half the expense have succeeded through selecting or rather being in possession of a favourable situation. Unnecessary shading or coddling is just as bad as the other extreme, but by having your Roses in a good situation, and all or nearly all together, how much easier it is to attend to their daily wants!

See what can be done with soft-soap, water, and a syringe, in the shape of cleanliness, and also note how dearly we pay—under new names—for what may be bought at 4d. per pound. These new baptismal processes are said to kill green-fly, red-spider, mildew, canker, and a whole host of other diseases—anything, in fact, but the Vine Phylloxera; and they have also been known to do irreparable damage in all sorts of fruit-houses, for the higher the price you pay the more powerful it becomes in its effect. Now as this short article is especially intended for non-professional growers, let me strongly recommend soft soap at 4d. per pound, sold under its own name, as the most simple and most effective recipe that can be used at the rate of from 4 to 6 oz. to the gallon, according to the hardness or otherwise of the Rose leaves and shoots at the time the liquid is applied by means of a syringe or fine rose.

If the collection is kept well together, the same advantages in feeding as in cleanliness will appear evident enough to the intending cultivator, should the soil happen—as is often the case—not to be a proper mixture capable of assisting Nature in producing Roses of a modern type. All these little attentions are sure to be neglected if Roses are scattered here and there and everywhere, and yet we wonder how it is they are not up to a certain standard of perfection. We now come to the question of pruning in spring. How and when shall we do it? For my own part I must confess to being often somewhat puzzled. I have decided against early pruning, but not so "thinning." We thin out all the unnecessary and weakly growths early, so that at pruning time we may have only to shorten according to judgment or circumstances the shoots that are left. Suppose any one has, like ourselves, a small spare plantation of Roses that can be pegged down, it will insure an early supply of Roses—that is, in case standards and half-standards suffer to an injurious extent through frosty winds experienced during the spring months. I recommend "layering" to facilitate the work of protection, which cannot be so readily given to the standard section, but even those may be protected in a great measure by having recourse to dried Asparagus litter, which is a wonderful protection, and a clean one, and offers but little obstruction to air and light. If those for whom these few hints are penned do not adopt my view of the case, my object will be gained all the same if those who reject it are on the alert next spring, and try what remedy they think best or have at command in order to prevent "Jack Frost" from slaying the Rose harvest. *W. Hinds, Otterspool.*

OUR SELECTION OF ROSES.

THE following list includes seventy-two of the most useful "all round Roses" in cultivation at the present time. To further assist Rose growers of smaller means we have marked a selection of forty-eight of the above with an asterisk *, thirty-six with †, twenty-four with ‡, and twelve with §.

| Cheshunt Hybrid | Princess Louise |

ENGLISH ROSES.

IT is quite impossible for us to give an adequate idea of the vast numbers of Roses grown by English nurserymen. Every nurseryman, more or less, is a Rose grower, and the quantity sold is enormous. Acres upon acres are devoted to their culture throughout the country, while the amount of glass devoted to pot Roses, or to purposes of propagation, is also very large. One of the sights of that well ordered nursery, Smith's of Worcester, is a long range entirely devoted to the propagation of Tea Roses grafted on the Manetti.

The names of those who make Rose exhibiting and Rose growing a speciality, are familiar in our mouths as household words. The reader has but to turn to our columns to-day to find that the rosarians of the present are no unworthy successors of those who have gone before.

While France may fairly claim *la gloire* of having been the nursing-mother of by far the largest number of notable Roses, yet there are signs that England is no longer going to be left behind in the race, and we may safely venture to back our Pauls, our Turners, Cranstons, and others for scientific precision in Rose raising, as well as for the results obtained. The French are a more logical and systematic nation than we in most things, but we very much doubt if the English raisers have not manifested a great deal more science in their procedure in this particular matter than the French. Amid the numbers of Rose books also, Mr. William Paul's *Rose Garden* stands out, not merely as a practical guide to culture, but as a model of scientific reasoning and observation applied to practice. Mr. Rivers' *Rose Amateur's Guide* is also a veritable treasure-house of lore and original observations connected with the Rose. Of books devoted to practical cultivation chiefly there is a large selection, and while they vary considerably in scope and treatment there is not one but is good. We cite, lastly, a few of the best known English Roses, with the name

of the firms by whom they were sent out, and, in some instances, raised. Much more credit is due to the successful raiser than to the merchant who merely purchases a good Rose which he procures in the ordinary way of business, and then sends out to the public with his name attached thereto.

WHAT TO LOOK FOR AT THE ROSE SHOWS.

AMONGST the numerous visitors to the leading Rose shows it is certain that very few possess that knowledge which enables them to form a correct notion of the various specimens before them, and to make profitable selections for their future use. Dazzled by the wealth of beauty before their eyes, they mark down from the tallies the names of such varieties as, from the colour, size (for sensationalism prevails even in Rose showing), or some other quality of their flowers, strike their fancy, utterly ignorant of their true character under culture. What wonder that such a crude and unwise proceeding should so often be followed by disappointment. The rash and inexperienced therefore should be cautioned that there is no test of the merits of Roses so fallacious as the "stands." It would be as wise to purchase a horse without warranty or trial as to order a Rose merely because it forms one amongst a prize collection.

For the assistance of the inexperienced it will be well therefore at this period to make a few remarks upon some Roses which are less known than certain favourites whose reputations are well established, and with the characters of which most rosarians are well acquainted. These varieties for the most part are to be found amongst the issues of the last five or six years, the novelties for the current season being few in number and merely upon trial. They are necessarily the produce of young plants grafted during the winter and spring, or of the few imported "stools" after they have been severely cut back to furnish scions.

TEA ROSES.

The "Teas" will be noticed first, as the class most generally known, and of which the fewest are brought out. A few acquisitions have been made in these, of which the seedlings from Gloire de Dijon are the best. Madame Berard is especially fine, vigorous and hardy, more rosy salmon than its parent. Next, Belle Lyonnaise, more yellow. Madame Lévet, Madame Trife, are likewise from Gloire de Dijon, not so fine as those previously named, but sufficiently hardy to be grown out-of-doors. Catherine Mermet is one of the finest of the class, flesh-rose, vigorous, and fairly hardy. Other Teas for special notice are Marie Gaillot, Cécile Berthod, Marie Van Houtte, Perle des Jardins, a fine

yellow; Madame Margottin and Madame Jules Margottin, Souvenir de Paul Néron, Jean Pernet, yellow; Mons. Furtado, clear sulphur-yellow. Old Niphetos ought to be marked by those without it. These are all good and safe either for culture under glass or out-of-doors where Tea Roses may be grown at all.

HYBRID PERPETUALS.

Next in order let us refer to some H.P.'s:—Marie Cointet, which burst upon the Rose world like a surprise at the Crystal Palace some two or three years ago, is a striking instance of the necessity of caution in buying Roses from show blooms only; some nurserymen did not even have it in their lists, yet on that occasion it was really beautiful—it has not been seen in the same form again. It is a bad

colour; Mr. Wm. Paul's new beauties, Queen and Star of Waltham, Magna Charta, and Queen Eleanor, La Souveraine, large, after Madame Clemence Joigneaux; Madame Louis Lévêque, Reine du Midi, François Fontaine, St. George (Wm. Paul), one of the finest dark Roses; Triomphe de France, said to have been specially so named in France. Subject to qualifying remarks, these are noteworthy Roses. It must be understood, however, they are not pointed out to the prejudice of such well-known favourites as Alfred Colomb, Marie Rady, Charles Lefebvre, Marquise de Castellane, and the like, which are certain to be in fine order whenever they appear.

One of the more modern classes in the schedules is that for the best twelve of any single variety. In many respects this is the most important section in

They are Duchess of Sutherland, William Jesse, rarely seen; Baronne Prévost, and La Reine—seedlings from the two last frequently now being sent out. The rapidity with which new Roses, like meteors, appear and disappear may be judged of by noting the best of the decade following those named above. Foremost in order of time and merit stands the once famous Géant des Batailles (Guillot père), then deemed a marvel of colour, but now relegated, not altogether undeservedly, to the realms of oblivion. Others were Mrs. Rivers, Auguste Mie, Caroline de Sansalles, Comte de Nanteuil, William Griffiths. These were all beautiful Roses, but lacking in some quality to hold their own against present rivals, and consequently are gradually falling out of sight. In 1853 the justly celebrated Gloire de Dijon first appeared;

FIG. I.—A TRAINED TREE ROSE.

grower, and equally bad or propagation. So is Lacharme's Captain Christy, about which so much talk was made. For one bud that takes a dozen probably will fail. Besides, it is not equal to that admirable doer, Mdlle. Eugénie Verdier. Marie Finger is something in the line. The beautiful tinted white Marquise de Mortemart is a delicate grower. Take the following as distinct and good, and suitable for amateurs:—Auguste Rigotard, brilliant red; Baron Bonstetten, very dark; Comte Raimbaud, dark carmine, a fine colour; Comtesse Serenyi, light; Comtesse Vally de Serenyi, amaranth-carmine; La Rosière, dark—fine dark colours are scarce; Hippolyte Jamain, in the line of Comtesse d'Oxford; Antoine Mouton, after Paul Néron; Mons. Noman, fine, but uncertain. A similar remark applies to François Michelin, which upon occasion also took rosarians by storm. Duchesse de Vallambrosa, superior to Captain Christy; Mons. E. Y. Teas, a fine bright red; François Courtin, purplish, distinct in

any exhibition, inasmuch as it not only shows the relative repute in which certain kinds are held by professional growers, but it indicates the blooming power, so to speak, of special sorts, as it is much more difficult to cut twelve flowers sufficiently perfect for show purposes at a given date than thrice the number of single blooms, even in the largest collections. The kinds appearing, therefore, in the class of twelve singles are tolerably safe for adoption.

ROSES OF THE LAST GENERATION.

The perfection to which the Rose as a flower has now attained is of comparatively recent date. Fifty years ago, before the discoveries of MM. Laffay, Vibert and Desprez, &c., Hybrid Perpetuals and the magnificent specimens of Tea-scented China were unknown. Out of their numerous productions only four of these pioneers of progress now remain, and these are still sometimes seen on the stands, though scarcely considered to rank amongst the first flight.

a variety of such super-excellence and rare utility that it stands quite alone—La France, amongst very recent introductions, being its only rival in versatility, though in a different line.

The year 1855 forms one of the epochs in Rose progress, inasmuch as we had Jules Margottin (Margottin père), and Général Jacqueminot (Rousselles), two varieties that have left their impress in separate lines, and which still perpetuate it year by year, in the guise of seedlings surpassing even their parents. Duchess of Norfolk, Lord Raglan (from Géant des Batailles), and like other progeny of that variety rarely seen; Duchess of Orleans, La Ville de St. Denis, Gloire de Vitry, Madame Domage, Madame Vidot, and Madame or Duchesse de Cambacérés, were also fine Roses, some of which are yet seen upon the tables, and are yet used for producing seed. Prince Leon, of the same date, once considered as the most symmetrical of Roses, has virtually gone out of cultivation, on account of its unsatis-

factory habit, the difficulty of successfully propagating it. Madame Knorr, most lovely in the bud, belongs also to this period, also Louise Peyronney. Then, again, came Souvenir de la Reine d'Angleterre and Triomphe de l'Exposition, two extra large flowers, though something of the roughest, and both well-known seed-bearers. In 1859, Anna de Diesbach, the first striking discovery of Lacharme, who has since done so much towards enriching the roseries of the world by some of their finest ornaments, came out, the model of symmetrical close flowers; Comtesse Chabriland (Marest), also Anna Alexieff, scarcely now a show flower, but excellent in pots or in the garden. Guillot père in 1860 issued Sénateur Vaisse, the finest of the crimson-scarlet class, of which there are so many high-class representatives, since thrown somewhat into the shade by Lacharme's Alfred Colomb. 1866: Louis XIV., an exquisite colour, a dark arterial blood, came in the same list. This Rose would be invaluable were it a thrifty grower, but no stock suits it, and it has consequently declined in demand. The Duke of Edinburgh is the only Rose that surpasses it in richness and brilliancy of tone. Continuing the same year's list, Madame Charles Crapelet, a fine Rose, but surpassed by Mr. William Paul's Beauty of Waltham; Duc de Cazes, an excellent Rose; Madame Furtado, a model of the Cabbage Rose type, but unfortunately a bad doer. About the same time likewise, these charming perpetual Bourbons, Baron Gonella, Catherine Guillot, and Comtesse Barbantanne, were worthy additions to our Rose grounds; more distinguished for symmetry than size, they are seldom now seen in the competition-boxes at our shows. 1862 was the rosarian's *annus mirabilis*—the year of years. Never before nor since were so many gems presented for our admiration, but we must reserve the notice their transcendent merit deserves for a future paper. *W. D. Prior, 25, Blurton Road, Clapton, E.*

THE TRUE HISTORY OF A ROSE.

A BOTANICAL description even of the loveliest flower is not very lively if regarded as a literary production, nor indeed is the florist's enumeration of the points of the fairest Rose that ever bloomed much more entertaining. Personal interest is lacking to animate the whole. Even the facial characteristics of Mr. William Sykes would be uninteresting to the readers of the Penny Dreadful, if they were not accompanied by some record of his deeds and sayings. It so happens that the history of a well-known Rose is associated with some gentlemen whose names might have figured appropriately in the *Police Gazette*. But lest—on the principle that a man is known by his companions—an odium should be thrown on a young lady of unsullied purity and untarnished reputation, I proceed to relate the following veracious history. By this it will be seen that if the lady should be brought into court (as happily she is not likely to be), she will assuredly leave it again without a stain on her character.

Some three or four years ago, from information received, I was induced to go and see a Rose whose characteristics were described to me as something out of the common way. The Rose had bloomed three years in succession, always preserving its special features. I went, I saw, I won my prize, at the expenditure of a large sum of money. My acquisition had four "eyes." To make sure of them, I destroyed the rest of the plant. The sport—for sport it was—was evidently a Tea Rose of unusual merit. On my homeward journey I wrapped my treasure in a piece of newspaper, and placed it by my side on the seat of the railway carriage, together with another travelling companion, my umbrella. Towards the end of the journey, however, I was called into another compartment to speak to a friend, and with him I rode to the end of the journey, some eight miles, leaving my packages behind me. What was my dismay on returning to the carriage I had quitted *en route* to find neither Rose nor umbrella. Here was a catastrophe! My money sunk, my anticipations blighted, my umbrella vanished, my beautiful Rose annihilated. What could be done?

I remembered that I had left two men of very suspicious appearance in the carriage, but I had no idea that in one stage of about eight miles only I could have possibly lost these things. It struck me, however, all at once that these men had my Rose and my

umbrella, too. The station at which I alighted was contiguous to another on a different line of railway, so I at once hastened to that other, but, alas! I could see no trace of the two men. On proceeding further, however, up in one corner of the station there was the newspaper, with the Rose in it safe and sound. The recovery of the Rose emboldened me, and gave me hopes for my umbrella. I was determined, if possible, to regain that also. I waited until the train was ready to start, when, as I expected, my former travelling companions appeared, one of them carrying my umbrella. I speedily regained that also, and my despair was converted into joy.

And now let me tell you the name of the Rose—it was Letty Coles. Never was a fine Rose so nearly lost to the lovers of Roses as this flower. I consider it myself wonderful, for had that paper parcel been thrown away the Rose would have perished, and Letty Coles would have been—nowhere. From those four eyes, however, the Rose has been propagated and distributed. It was a sport from Madame Willemoz, and fine flowers will, I trust, be exhibited this year. *John Keynes, Salisbury.*

OLD ROSES.

"WITHOUT at all denying the great beauty of many of the Hybrid Roses," writes Mr. Ellacombe, "I am sure that growers of hardy flowering shrubs do not know what they lose in so entirely ignoring the Roses as they do." We entirely agree with our correspondent, and think that one function of the Rose Society should be to extend the knowledge and promote the cultivation of these lovely flowers. As a means to this end we asked Mr. Ellacombe to be kind enough to select from among the multitude grown by him those species most remarkable or interesting as garden plants. In reply he has sent us the following list, but in view of the confusion of the nomenclature, he simply gives the names as he finds them, without accepting responsibility for their correctness:—

CABBAGE ROSE.—Unsurpassed for scent, the "Provincial Rose" of Hamlet.

MOSS ROSE.

DAMASK.

SCOTCH.—Forms most beautiful bushes, which are loaded with flowers in their season.

BANKSIA, white and yellow.—Is the single form in cultivation?

BRACEATA, OR MACARTNEY.—A grand single Rose with bright foliage. The double form is very inferior, as it wants the golden centre.

VILLOSA.—The old Apple Rose. Very effective as a lawn shrub both in flower and fruit.

GREEN ROSE, R. VERTE.—More curious than pretty.

MICROPHYLLA.—A charming Rose when well grown, and very distinct; very double, beautiful foliage, unlike any other plant, and with a curious prickly calyx.

ALBA.—One of the oldest English garden Roses, and most excellent, but seldom seen out of cottage gardens; pure white, double, but not very fully; probably a variety of *R. arvensis*, and almost beating the white Rose of York.

RUBRIFOLIA.—Curious for the colour of the stems and leaves, and handsome both in flower and fruit; single.

MOSCHATA.—The old Musk; a long rambling Rose, but very sweet, with clusters of pure white flowers.

YORK AND LANCASTER.—Very distinct.

ALPINA.—The Rose without a thorn.

ANEMONEFLORA.—Fortune's name for a very distinct form of *R. indica*, a small double cluster Rose.

MULTIFLORA.—The Bramble-flowered Rose. A pretty Rose, very like the double Bramble (see p. x.).

DE MEAUX.—An excellent old Rose.

R. RUBIGINOSA.—Double and single Sweet Briar.

AUSTRIAN BRIER.—Distinguished by its different colour on the outside and inside of the petals.

FAIRY ROSE.—Very dwarf, so that edgings may well be made of it. The new white one, Little Pet, is especially pretty.

MONTHLY CHINA.—Too much neglected. I know of no flowering shrub that can show such a succession of flowers as this. Does any one?

R. CINNAMOMEA.—A rambling bush, but the flowers very bright, and the long fruit very handsome.

Has any one got *R. Hardii*, *simplicifolia*, *sulphurea* single, and *myriacantha*?

THE ROSE IN FRANCE.

THE cultivation of Roses in the vicinity of Paris is a very important affair, and gives employment to several hundreds of people.

First of all, the Roses are grown as ornamental shrubs for sale. They are mostly grafted on the Briar, either as *tiges* (standards), *demi-tiges*, or dwarfs. The Manetti stock is very seldom used here, although

the case stands otherwise at Angers; the multiflora Rose, *La Griffardaye*, is sometimes, but seldom, used as a stock for standard Roses. About 250 acres of ground may be said to be devoted to the growth of grafted Roses around Paris. As the plants are left for two seasons on the ground, being cleared off and sold only at the end of the second year, the produce of half that extent only is put in the trade every year.

On an average, not less than 24,000 plants are put on an acre, but as nearly one-half fail to grow well, or are not successfully budded, the number of budded Roses sold from an acre seldom exceeds 12,000, giving for the total number reared in one year in the district around Paris 1,500,000, which estimate, if not quite correct, is rather under than above the mark. Of these about 300,000 are standards and 1,200,000 dwarfs.

To this must be added the *rosiers francs de pied*—Roses on their own roots—propagated by cuttings or layers. The Bengal and Provence Roses, together with several old kinds, are mostly propagated in this way, and if these are taken into account, the total number of Roses raised here in one year must be put at 2,000,000 at the least.

Roses are grown, moreover, for cut flowers: this is altogether a different matter, of which more hereafter. The great places for Rose culture are—Bourg la Reine, Ivry, Gentilly, Montmorency, Bougival.

A new centre of Rose culture has been established for some years past in a rural district somewhat farther from Paris—viz., in the neighbourhood of Eric Comte Robert, and especially at Grisy-Suisnes, Villecremes, Mandres, Santhey, and Conbert. The hardest kinds are chiefly grown there, and very large numbers of plants are exported annually.

The leading Parisian firms in the Rose trade are well-known in England, and it is scarcely necessary to mention to your readers the names of Margottin, Eugène and Charles Verdier, Levêque et Fils, Hipp. Jamin, Ferd. Jamin, Scipion Cochet, Duval, Granger, Gantreau, &c. These men, who propagate the best varieties, no matter where they come from, are also the raisers of some of the best new Roses. Margottin the elder is especially considered as a successful raiser, as many of his new plants have become popular in the garden and the market. This is the case in particular with Jules and Charles Margottin, Rev. H. H. D'Ombraïn, Triomphe de l'Exposition, &c.

Eugène Verdier has raised Duchesse de Morny, Prince Camille de Rohan, May Turner, Annie Wood, Madame Victor Verdier.

We are indebted to Charles Verdier for Madame Furtado, Vulcan, and the Bengal Rose, Madame Bréon. Scipion Cochet is the raiser of the very popular Souvenir de la Reine d'Angleterre. Gantreau, Granger, Lédéchaux, Fontaine, have raised also several good varieties. One of the most successful of raisers of a former generation was Lafay, who now lives at Cannes.

Novelties, however, find their way only very slowly to the cut flower market and to the gardens of the million. The kinds most grown here are most of them of old standing. The following are met with everywhere:—

The old Centfeuilles	Madame Bolle
Rose du Roi	Jules Margottin
Rose de la Reine	Madame Victor Verdier
Souvenir de la Malmaison	Triomphe de l'Exposition
Gloire de Dijon	Aimée Vibert
Souvenir de la Reine d'Angleterre	Céline Forestier
Baronne Prévost	Boule de Neige
	Général Jacqueminot

Of newer kinds the following are becoming general favourites and plentiful in every garden:—Maréchal Niel, Paul Néron, Auguste Nic, Baronne de Rothschild, Eugène Appert, Captain Christy, Duchesse de Sutherland, Thérèse Levêt, and Edward Morren. Many gardeners who never rear Roses sell them in pots at the flower markets, either forced in winter or as cut blooms in spring and summer. They buy the plants from the growers and prepare them for blooming under glass or in the open air. Nearly 300,000 are disposed of annually in this way. The sorts most used are:—Jules Margottin, Madame Boll, Baronne Prévost, Souvenir de la Reine d'Angleterre, Rose Centfeuilles, Rose du Roi, Anna de Diesbach, and Paul Néron. The dwarf, small flowered varieties of Bengal, as Miss Lawrence, are very extensively grown and sold in pots.

Another and a very important branch of trade is the cultivation of Roses for cut flowers. The headquarters of this branch of the trade are about Belle-

ville, Bagnolet, Montreuil and Charoone. Not less than 600,000 to 700,000 plants are devoted to the production of the flowers; they are generally dwarf plants on their own roots, and belong only to a few varieties which bloom very freely, as the old Moss Rose, Rose Centfeuilles, Pompon, Jules Margottin, Baronne Prévost, Rose de la Reine, Duchesse de Canbacères. Many of the varieties mentioned as grown to be sold in pots in winter yield cut flowers for the market. To these must be added Madame Falcot and Maréchal Niel, grown for buds, which sell at a high price for bouquets in winter. Scarcely a day passes but fresh, home-grown Roses may be procured at the flower market, or at the "Halles," besides the Roses sent from Nice or Florence. Even the petals of Roses are in great demand here, especially those of the Provence Roses; they are very strongly scented, and are sold, when fresh, to perfumers, and when dried to druggists. *Henry Vilmorin.*

— The great centre of Rose culture in France is situated in the vicinity of LYONS. The following names among the leading growers will be familiar to many of our amateurs:—Bernaise, Chartron (successor to Dumaizin), Dachet, Denis, V. Ducher, Guillot fils, Gonod, F. Lacharme, Jean Lapresle, Labryère, C. Levet, Liabaud, Rambaud, Pernet, Schwartz.

The quantity sent out yearly from Lyons varies from 700,000 to 1,000,000 of plants; the prices of the old sorts vary from 50 c. to 1.50 c. Nearly all the Roses are budded on roots of wild Brier (seedlings), and about 20,000 on their own roots, and the same quantity on standards.

F. Lacharme has raised many of the best Roses now in the collections, principally in Perpetual Hybrids; Guillot fils has also raised many, but principally Teas and Noisettes; Madame V. Ducher and A. Levé are favourably known as raisers, but principally of Tea Roses; Liabaud has also obtained some very good hybrids; Pernet and Gonod have sent out some good Roses. The others are principally propagators of the old sorts. *Jean Sisley.*

— Some idea of the extent of Rose culture in France may be obtained from the circumstance communicated to us by M. Camille Bernardin, that in the thirteen communes which surround BRIE COMTE-ROBERT, the birthplace of "Noisette," more than 2,500,000 Roses are annually cultivated, the number of growers being about a hundred. The Briers are procured from Burgundy, and planted 33 centimetres apart in three rows, and in beds 66 centimetres apart. The number of varieties grown has been estimated at from 700 to 800, though that is probably an exaggeration, as naturally it is the most robust and the greatest favourites which are most extensively cultivated. The origin of Rose culture in the vicinity of Brie dates back to 1799, the best known raisers of new varieties being MM. Cochet, Granger, and Rousseaux. We cannot stay to enumerate the varieties raised in this locality, but among them we may cite Edward Morren, Clémence Raoux, Charles Lee, and Comtesse de Jaucourt.

THE PROPERTIES OF A GOOD ROSE.

THE first and most essential point to constitute a good Rose is that the variety be hardy and of a healthy and moderately robust habit, combining ample foliage; for, be its blooms ever so good, if it refuses to grow under proper treatment it is almost worthless. Next to these are fine form, fulness, large size, good substance, fragrance, freedom to bloom, and decided and distinct colour. The form of the flower, whether it be cupped, globular, or expanded, should be symmetrical; the petals even and regularly placed, smooth, and free from all indentures, full, but not crowded, the outer row being broad and closely folded, to enable the flower to stand firm for several days. They should be thick and leathery in texture, and not (as we too frequently see them) thin and flimsy, and either faded or fallen to pieces after an hour's sun. The colour, whatever it be, should be decided and lasting, and not changing to dull, cloudy, or objectionable shade. The flower-stem should be stout, to hold the blooms partly erect, so that it may be seen without the

necessity of applying the hand. Every Rose should be fragrant, and the more highly so the better. Whether summer blooming only or perpetual, it should be free to flower, in the former case yielding abundance of blooms throughout June and July, and in the latter from June till November, allowing for an occasional rest between each period of flowering. A perpetual Rose, to justify its name, should always produce blooms at the end of each shoot. As examples of finely formed and perfect Roses the following may be instanced:—Cupped: Madame Vidot, Comtesse Cécile de Chabillant. Expanded: Madame Charles Wood, Souvenir de la Malmaison. Globular: Reine du Midi, La Reine. From "Cultural Directions for the Rose," by John Cranston.

— A Show Rose should possess—1, beauty of form, petals abundant and of good substance, regularly and gracefully disposed within a circular symmetrical outline; 2, beauty of colour—brilliancy, purity, harmony, endurance; and, 3, must be exhibited in the most perfect phase of its beauty, and in the fullest development to which skill and care can bring it. "A Book about Roses," by Canon Hole.

THE FAIRY ROSE.

ONE of the most pleasing flowers of early spring that comes into Covent Garden market, and meets with a ready sale, is the Lawranceana or Fairy Rose

FIG. 2.—THE FAIRY ROSE, SKETCHED IN COVENT GARDEN.

(a variety of *Rosa indica*), the first of which was introduced from China in 1810. These Fairy Roses have long been popular for pot culture and for edgings to Rose beds, growing no higher than about a foot, and when well grown covered with their tiny but exceedingly pretty blossoms. The first of the Fairy Roses generally make their appearance in Covent Garden as early as February, and the supply lasts up to May, or later. There are not many of the market growers who prepare any large quantity of Fairy Roses, and perhaps the Messrs. Hayes, of Edmonton, at the present time grow the greatest number of all. The plants in the proverbial 48-pots are exceedingly well-grown, as shown in the accompanying illustration (fig. 2), and for domestic decoration in their season there are no more interesting or more pleasing objects of care.

A GOSSIP ON ROSES.

"That sweet lovely Rose."—*Hamlet.*

ABOUT the time when Dr. Lindley published his monograph of Roses, M. Villarsci at Monza (a royal gardener) startled the horticultural world by his hundred seedling varieties from *Rosa indica*. Then followed in Britain a batch of sportive seedlings from the Scotch Rose. Here then was the beginning of all subsequent improvements. The latter history belongs to us, but does any Rose grower remember the period previous to the publication of Lindley's work? Before that is "improvement's innovation"; when the ill-developed Four Seasons was sold for double the price of our newest Rose of to-day—when *Semperflorens* was an

inmate of a greenhouse, and the Cabbage, the Tuscan, Maiden's Blush, and the Moss Rose were not absent from any single garden in the land; when Lee and Kennedy introduced such new French kinds as *Couleur de Feu* and *Carmine Brillante*; and when in carriages and on horseback people flocked to the popular Vineyard Nursery to see them in bloom.

Truly, Roses were loved singlemindedly in those days. Basket-beds were formed with them upon lawns; in many instances strong-growing kinds were grown and twisted over so as to form the handle, and in this position the double cupped rose-coloured Drummond's Thornless, of *Rosa alpina* origin, formed a smooth, rounded, and twisted handle. The dwarf and variously-coloured Scotch Roses were judiciously planted below, and when in bloom during the fifth month may well have given rise to the exclamation—

"O Rose of May."—*Hamlet.*

Roseries, in huge beds of a horse-shoe pattern, but interlaced so often that, to get to the centre, a labyrinth or maze had to be traversed, consisted of species, or the first "flushed" improvements of *Rosa gallica*, *R. alba*, *R. indica*, *R. centifolia*, *R. damascena*, &c.; whilst for smaller beds the lovely Rose de Meaux was all in all.

Then, as now, the most valued bouquet for a princess or a peasant's daughter would consist of such older kinds as these and others—buds and blooms culled from the violet-scented white-flowered *Bank-sian*, or half-opened Moss Roses, which possess a singular rosebud odour, unique in themselves, for even in matter of fragrance,

"Masked are Roses in their bud."

Love's Labour Lost.

What should we say were our gardens suddenly restored to their former state, and we were again familiar with beds of the true old double Provence, the origin of which is doubtful? The normal kind has at times been confounded with the Damask, though its name is derived, no doubt, from that district in France from whence so many were brought for the Paris markets. This smaller double or normal form grows wild on the southern banks of the Caucasus, by no means an exception, as Italy boasts many double forms growing in a wild or half wild state. The White Provence, Crested Moss, &c., are intimate relations of it. This is the Cabbage Rose, bearing fragrance as of old Cabbages! And the old Moss Rose is but a sport from it, for it is notorious that the Messrs. Lee once possessed a plant bearing the original and the sport both on one stem, and subsequently many similar cases have been noted.

Where are the Striped Moss and Laffay's Perpetual, striped and very beautiful, with red and rose-coloured bars? We should not, with our more intimate knowledge, mistake the older, smaller "Provins" for the larger ones sometimes seen, and which was once known as the larger or "greater Holland Rose"—the showy large flower which, no doubt, Shakespeare referred to when he wrote—

"Two Provençal Roses on my razed shoes."

Hamlet.

When shall we meet again with beds of York and Lancaster, having red and white coloured blooms; or with such old favourites as the Village Maid, prettily striped, and called variously *Provins panchée nouveau*, *Belle Rubanée*, &c.? Another lovely form, named *Picotée*, possessing dark purple velvet petals, striped with white, has disappeared, as have also *Tricolor*, or *Belle Alliance* and *Rose Marguerite*, &c. All these were of French origin.

Every one knows the *Rosa lutea*, but the variety named bicolor or the copper Austrian Briar is scarcer. A branch in bud and bloom lies beside me; the similitude of its colour to new copper should not have prevented it from being called the Scarlet Rose. It is a lovely object, on which we could dwell long in the contemplation. But we lay it aside, with its five rounded petals and its elegant yellow stamens, to pick up Macartney's distinct forms, with lovely shining dark green leaves; the hybrid *Maria Leonida*, with large, concave flowers with a white centre, blushing as it expands from the bud form. The original single forms, vera and scabricalis, are noteworthy and meritorious.

The Scotch Roses will not readily be lost. Like the ruddy mountaineers of their native country, they live whilst others starve, and insinuate themselves into any soil, upon any ground, to attain the precious root-hold.

for life and living. But, unfortunately, we have to ask, where are they all? Where are the lilac Marquis of Townsend, the crimson-purple Lady Hutton, the cupped Duke of Hamilton, the striped Hector, and the blotched Monstrosa, all of which ought to be in every garden—certainly in every Rose garden. The lovely white or *crème* Marquis of Queensberry bushes of which we have planted as edgings to our rosery-beds, is now in full bloom. The edging, being a foot in height, 1 foot across, and about 200 feet in length, is exceedingly handsome.

We have lost sight of the Magnolia-scented moisture-loving Pompon Jaune—some older branches of the famed Bourbon family, so popularised by the incessant blooming of our modern Queen of the

contrary to the general notion, is white-flowered. The flowers hang in clusters in their eastern defiles, and are associates with the Persian nightingale. The Musk Rose is autumnal, and should not be mistaken for the clustered forms of Damask, as it too often is; the good old Madame Hardy being a Damask of this type. It is to be feared that the original species is not to be met with; *Moschata nivea* comes from too eastern a clime to be able to bear neglect within our latitude.

Older Pompon Roses, such as that gem, Rose de Meaux, which is so exceptionally pretty, though not too free of growth or propagation, increase tolerably freely by layering. The Pompon Varin (Spong's Rose) was once greatly used for forcing. The Pom-

Village Maid be staged with Kean, if the latter still exists upon life's stage—the Damask with Madame Zoetmans—"a worthy sire and a worthier son!"—Harrisoni, or Persian yellow, with the Austrian copper!—the Macartney alba simplex with fair and blushing Maria Leonida—the old Moss and Mrs. William Paul, and so forth. Break away from convention and wearisome stereotyped iteration. Seek more variety and better arrangement. Make "old Roses the rage," as are now the new, and a fresh branch of industry will arise which will push floriculture beyond its present standpoint, bring beauty to the fore, bring back to us the primitive fragrance, and renew the enfeebled constitution of our Roses. *William Earley.*

FIG. 3.—SPECIMEN PLANT OF CHARLES LAWSON (H.C.), GROWN BY MESSRS. PAUL AND SON, CHIESIUNT.

Bourbons. They all originated upon the Isle of Bourbon, between the Rose of Four Seasons and *Rosa indica*, and were such as Rose Blush, White Blush, Blush Four Seasons, with many "charming cousins," as Crimson Perpetual, the striped Quatre Saisons panachée, the Lettuce-leaved Bullée, &c.

The rusty Sweet Brier, to translate its Latin name, is of singular distinctness. How few are there who know more than the one common kind. But what of the yellow Eglantine?—that Eglantine which Lord Bacon once mistook for a very different flower, and which even in Gerard's day was "a prime rarity." The hispid Sweet Briar, the Rose Superb, and the Chester, seem also to play us truant.

And the Musk Rose, thought to be the true Persian, and on which the Persian lyre so often lavished tones of joy—which Persian poets so often associate with their thoughts of beauty—this, con-

pon à Centre Pourpre (purplish centre) is, we fear, lost. Then of Miss Lawrence's Liliputians the so-called "Fairy Roses" may still be seen in the tiniest of pots in Covent Garden Market: where now are La Monche, probably the truer "Fairy," Gloire de Lauranceana, Liliputian, and the "Heaven sent," Dieu Donné? If lost the loss is great, however small the flower.

An exhibition which is likely to do so much for the newer forms, by bringing them into public favour, ought to aid in the reintroduction of those delightful old kinds to younger votaries and others who may have little knowledge regarding them. Granted *Maréchal Niel* has earned a well-merited place at exhibitions, why should not the gallant *Maréchal* be staged *vis à vis* with the most primitive example of *Rose à odeur du Thé*, or with *Jaune Desprez*, if a more aged relative cannot be found? Let *Belle Alliance* or

CULTURE OF ROSES IN POTS.

As we are now just entering a new year, as it were, for Roses in pots, a few hints on their culture may prove advantageous. The flowering season, generally speaking, being now over, those that have not already been repotted should be potted at once, to encourage a free growth, which is very essential, as it forms the groundwork for next year's flowering. The best compost is two parts of good rich yellow loam, one part thoroughly decomposed manure, with the addition of a little leaf-mould and good sharp sand well mixed together. As soon as they are repotted, place them in a cool house or pit, and sprinkle overhead with a syringe morning and evening.

Should the weather be very bright, a slight shade will be necessary for the first week or so, until such time as they have fairly made root, when they

may be gradually hardened off and placed out-of-doors, and remain there until autumn, when they should be brought back to the house or pit, giving them plenty of air day and night, except in very severe weather. Keep them tolerably dry through the months of November and December.

Plants that are required to flower early in March should be pruned in the early part of December, if wanted earlier they will require a little more time. In

until the buds show signs of opening. Shading will be necessary to protect the flowers from the hot sun as they open, and should be continued according to the weather until they are out of flower.

As there are so few Roses that are really good for pot culture, I append a list of the very best, good foliage being most essential as well as fine blossoms:—John Stuart Mill, Royal Standard, Alba rosea, Camille Bernardin, Céline Forestier, Beauty

THE ROSE AND ITS ENEMIES FUNGI.

It appears to be one of the compensations of life, animal and vegetable, not only that all which is fair must fade, but that all which is beautiful should have its foes which seek to destroy its beauty, and bring it down to the level of ordinary common-place things. This is especially true of Roses, which, though amongst

FIG. 4.—SPECIMEN PLANT OF PAUL FERRAS (H.C.), GROWN BY MR. TURNER.

pruning cut away all weak surplus wood, leaving only such as will be likely to flower; cut them back to about three eyes, except the very strong growing varieties, which may be left from 3 to 6 inches. Care must be taken not to over-water them at this particular period, or they will break weak; start very gently at first, increasing the temperature as the plants advance, sprinkle overhead with the syringe in the morning in fine weather, as that will greatly assist their breaking. As soon as the flower-buds are set, a little manure-water should be given. Continue syringing overhead every morning in fine weather

of Waltham, Edward Morren, La France, Juno, Miss Hassard, Duke of Edinburgh, Madame Lacharme, John Hopper, Madame de St. Joseph, Rev. J. B. M. Camm, Madame Victor Verdier, Madame Willermoz, Miss Ingram, Dr. Andry, Mdle. Thérèse Levet, Maréchal Vaillant, President, Victor Verdier, Marie Van Houitte, Marquise de Castellane, Marie Baumann, Perfection de Montplaisir, Souvenir d'un Ami, Princess Beatrice, Paul Verdier, Charles Lawson, Camille Bernardin, Madame Margottin, Horace Vernet. Charles Turner, Slough.

the most beautiful of flowers, have as many spiteful enemies as jealousy and envy could desire. Unpleasant as it may be to call attention to these misfortunes at a time when all are singing the glories of the Rose, it was nevertheless an old custom even at a feast to bring in mementos of death, in order to remind those who were supposed to have attained the climax of enjoyment that there was a final destiny to which all must succumb.

Homilies on disease and death are by no means welcome topics to be introduced at seasons of enjoyment, and it will perhaps be regarded as *mal à propos*

on our part to cast a gloom over the feast of Roses. There still remains the consolation that the contrast may enhance the beauty and intensify the odours of sweetness, so that the jewels may shine more brightly than one which "has no foil to set it off."

Those who are most intimately acquainted with the Rose know best that its foes are numerous, and even if we do not reckon the insect marauders there remain still a very sufficient list for a homily.

RUST AND BRAND.

Of these the best known, and perhaps least respected is the "rust." Minute description of such a well-known parasite is unnecessary. A sickly jaundiced hue takes possession of the whole plant, the under-surface of the leaves is sprinkled with a golden-yellow dust, which in time becomes mingled with little black specks, and with a tenacity worthy of a better cause the "rust" and the "brand" together maintain possession of the foliage till it falls to the ground, and nothing remains but the gaunt skeleton. Should the gods have bestowed upon us sufficient equanimity to enable us to investigate still further the source of so much mischief, we shall find by aid of the microscope that the orange dust consists of myriads of nearly globose yellow cells, mixed with a less number of colourless cells of slightly different shape. Earlier in its history the barren cysts and the orange cells would have been found together, supported on slender stems, and collected in clusters. But still more imposing are the black specks interspersed amongst the orange powder. These consist of sausage-shaped bodies, of a deep brown colour when magnified, standing upon uncoloured slender stems about as long as themselves. Each of these brown bodies is several times constricted, as though some slender cords were tightly bound at equal distances around them, and moreover the surface is studded with little glassy warts. In the catalogues of science the names which are given to the "rust" is *Lecythea rosarum*, and to the "brand" *Phragmidium mucronatum* (fig. 5.) At one time each was regarded as a distinct and separate parasite, but now, on the contrary, it is maintained, for excellent reasons, that the one is but a condition of the other, and that all these manifestations are but different phases of the same unwelcome guest.

MOULD AND MILDEW.

Another enemy makes its appearance in the autumn which has kindred with the Hop mildew, and less intimately with the Vine mildew. This mould on the leaves and young branches gives them a frosted and, on the latter, a grey woolly appearance. The *Sphaerotheca pannosa* derives its specific name from the woolliness of its patches on the petioles and branches. It is not so common to find the complete fruit fully developed, but when this is the case small, globose, dark brown conceptacles or hollow cases appear on the woolly threads, and these contain a single sporangium or spore case with eight sporida. It is deplorable to see the melancholy condition of Roses under this infliction—the leaves are puckered and blistered, the flower-buds and calyces are darkened and distorted, and altogether the plant is comparable only to some poor unfortunate individual stricken with paralysis. The imperfect condition of the parasite is sufficient for all this mischief.

Fifteen years ago another parasite on Roses first made its appearance on a quantity of pot Roses in a conservatory, and was figured and described in this journal,* by the Rev. M. J. Berkeley, under the name of *Peronospora sparsa*. It is certainly the most uncommon of the pests to which we have had occasion to allude, and it is hoped will still remain of rare occurrence. In this instance the affinity of the fungus is with the Potato mould, and if we may judge from its family connections it is likely to be a most devastating pest should it ever become thoroughly established. Irregular pale brownish discoloured spots appear on the upper surface of the leaves, these extend rapidly, and in a short time the leaves become withered and shrivel up, and ultimately the whole plant perishes. A delicate greyish mould is to be seen by the aid of a lens scattered over the under-surface of the leaves, and a higher magnifying-power reveals branched threads surmounted by oval bodies having the appearance of spores. It is not clear that the whole history of this parasite has yet been revealed; it is not improbable that these spore-like bodies, or conidia, may, as in some other species,

become ruptured when mature, and scatter numerous movable spores or zoospores, each of which, after a short period of active motion by the aid of vibratile cilia, may settle down and commence germination. Should such be the case it is a formidable foe to contend with, and should be at once condemned whenever and wherever it ventures to make an appearance.

Although these are the three most important of the diseases caused by fungi to which Roses in cultivation are subject, there are still one or two others to which allusion may be made. Late in the year roundish purple-brown spots, half an inch in diameter, may be seen on the upper surface of Rose leaves. If these are examined closely the spots will be seen to consist of radiating threads, with here and there small round bodies, like little black dots, seated upon them. This is called *Asteroma rosea*. Perhaps its power of destruction is not great, but it imparts an unwelcome kind of variegation to the leaves, which could well be dispensed with. Each of the little black dots is a receptacle containing a number of spores, each divided by a single partition, by means of which the stock is prevented from dying out.

Some years ago we observed in one large garden at some distance from London that nearly all the trained Roses had the branches disfigured by the scaly blotches of a fungus known as *Dothidea rosea*. In this instance the spots are also circular and brown, often several running together, and occupied by raised

FIG. 5.—ROSE BRAND.

circles, one within the other, of the darker conceptacles which contain the fruit. When it appears in such force, as in the instance alluded to, it is undoubtedly destructive, for many of the Roses were entirely spoiled, but such an instance is probably rare.

It is hardly necessary to allude to *Septoria rosarum*, which is by no means uncommon on the fading leaves of Roses. Small grey spots are surrounded by a purplish border. The central pale spots are occupied by a few small black dots, which are embedded perithecia, or cup-like cavities, containing the minute spores. When mature the latter are ejected from a pore at the apex.

Rapidly and cursorily we have indicated the "foes of the Roses" coming under our special cognisance as of fungoid origin. Although not so numerous perhaps as the foes of some other plants, they include some which are pertinacious and destructive enough to compensate in quality for what they want in quantity. Let us hope that the majority of our readers, especially those largely interested in Roses, suffer but little from their devastations. *M. C. Cooke.*

THE ROSE AND ITS ENEMIES : INSECTS.

THERE is a great difference in the number of species of insects that attack different plants. Some plants seem to be wholly free from them, as, for instance, Fumitory, Stock, &c.; others have only a very few enemies. The Wallflower has about half-a-dozen, the Poppy about a dozen, and so on. On the other hand, the numbers that attack some trees are

very large. Nearly 250 kinds are recorded as preying on the Plum tree, about 180 on the Apple, Pear and Quince, and about 100 on the Thorn; but it is some of the forest trees that support the greatest number. There are upwards of 250 recorded as preying on the Poplar, about 400 on the Willow, and upwards of 500 on the Oak. The Rose occupies a sort of middle place, there being only about 100 recorded as attacking it in Europe. When the Editors of this journal asked me to give a *resumé* of the species that attack the Rose, I am afraid they scarcely knew what an avalanche they might bring down upon their heads. All that I can do within such limits as they place at my disposal is to give a few hints which may help rosarians to form some guess, from the mischief done to their Roses, as to the species that is doing it. Beginning with the lower orders of insects, the scale insects come first. Of these only one attacks the Rose.

SCALE INSECTS.

Diaspis rosea, Sand.—When a Rose tree is badly attacked by this, its stem and branches seem covered by a mealy crust, looking somewhat as if the plant had been badly whitewashed. The scale is a small, roundish, flat, white fluke, with the mark of the first moult or moults towards one side of the scale instead of in the centre. That is one of the chief distinctions between the genus *Aspidiotus* and *Diaspis*.

The best remedy for this is the knife, and as with most Roses it may be used freely without harm, the attacked parts should all be cut off and burned.

GREENFLY.

Next comes the greenfly: of these several attack the Rose.

Aphis rosea (*Siphonophora rosea*, Koch).—This is the commonest of the Rose aphides. It is greenish or pale reddish green in its young stages; green, with blackish spots, in its winged state. Several other species that infest the Rose have been described, viz., *Aphis rosarum*, *Aphis dirhoda*, *Aphis trithoda*, &c.

Typhlocybe rosea.—One of the small jumping spittle flies that breeds on the Rose. It is yellowish, and in autumn often starts up from the plant in greater or less numbers on any one's appearance.

THRIPS, &C.

Thrips minutissimæ.—We often see the leaves of our Rose trees lose their freshness, becoming hard and getting whitish on the convex parts, as if the nap was worn off the surface. This is the work of the thrips, and is very easily recognised.

Forficula auricularis.—The common earwig, although certainly not a special enemy to the Rose, sometimes destroys its petals and occasionally shows his unwelcome presence among them.

Trypeta (*Spilograpta*) *alternata*, Mig.—This is a fly with banded rings, that feeds on the flesh of the fruit of the Rose, mining in it and deforming and affecting its colour; that is, making it partially white where it should be red. It occurs in Germany, but I do not know whether it has been found in England or not. Certainly deformed and parti-coloured Rose-hips are not rare there.

A large number of hymenoptera attack the Rose. There are several species of cynips that make galls upon it, and a special genus, *Rhodites*, has been made for a portion of them.

Rhodites rosea, Linn.—This is the species called the Rose bedeguar, which produces the curious mossy galls (Robin's Pincushion) that are found on the Rose tree. It is common in Britain, and at least one other species (*R. nervosa*) has also been found, although its gall is not known. Several species occur on the Continent and in North America.

SAWFLEES.

The sawflies that attack the Rose are rather numerous.

Elytoma rosarum, Fab. (*rosea*, Linn.), is the one that fixes a chain of eggs on the under-side of a shoot, causing it to bend downwards. The perfect insect has a black head and thorax with a red body; the larva is yellowish on the back, greenish yellow or bluish green on the sides, whitish below, and peppered over with black spots. It attacks the leaves from the margin, eats large spaces out of them, often eating up everything but the ribs, which hang or stick out like dishevelled shreds. An easy mode of diminishing their numbers where they are formidable is to grow a few plants of Parsley near the Roses. To

these the fly retires about mid-day, where it can be easily taken and destroyed in numbers.

The *Athalia spinarum*, Fab., or *Centifolia*, Panz., is like the preceding in appearance, but although it is found in gardens in autumn flitting about in the sunshine, it does no harm to the Rose. The Turnip and Cabbage tribes are its food, and it is well known to the farmer under the name of Black Jack or Nigger, the larvæ being almost black, with a slight tinge of green.

Athalia roseæ, Linn.—Smaller but similar to the

FIG. 6.—ANTLER ROSE SAWFLY.

preceding, more yellow. This is sometimes very common, and it is its larva that converts the leaves into skeleton network. It does not eat straightforward, like the other, but browses away upon one side only, eating up the parenchyma, but leaving the nervures and the skin on the other side like a transparent wall.

Blennocampa athiops, Fab.—For a length of time Linnaeus' name, *Tenthredo athiops*, was applied to the slug-sawfly of the Pear tree. Westwood showed that this was an error, and that the name properly belongs to this species.

The peculiarity of the ravages of this species is somewhat similar to those of the last. It only eats the upper side of the leaf, but does not go so deep nor so thoroughly through it as the last does. Instead of leaving a transparent wall on the under-side it leaves a brown one. It is at the beginning of June, when the flowering of the Rose is commencing, that its attacks show themselves. Until then everything has looked fresh and green, but all at once the leaves become of a pale brown, as if they had been scorched by a sunstroke, and on examining them with attention they are found to have been attacked by the larva of this species in the manner above described. It not only destroys the freshness of the appearance of the Rose, but makes the flowers come badly, from want of nourishment. The larva is pale yellowish green, scarcely distinguishable from the Rose leaf. The perfect fly is shining black except the legs.

FIG. 7.—THE ROSE SAWFLY.

Blennocampa pusilla, Khy.—It is only a few years since this species was recognised as British, but its presence can very easily be guessed at by the appearance of the leaves attacked. These have the edges of the leaves rolled in on the under-side until they almost meet at the midrib, and on unrolling them the small larvæ may be seen—yellowish green, darker on the sides, whitish below. The perfect fly is small and shining black, all but the legs from the knees, which are dirty white.

Monophadnus bipunctata, Khy.—This species lays its eggs on the tips of the young shoots, down which the larva afterwards bores through the pith, but I do not know that it has been met with in Britain. It is

a black species, like the last. Its larva is probably sometimes mistaken for the next species, and, according to Taschenberg, has been so by Boisduval, who, he thinks, has jumbled up the habits and characters of the two species together.

Emphytus cinctus, Linn.—This species is common enough in Britain, where it is generally understood to be a borer in the Rose stems. According to Taschenberg, however, it only feeds on the leaves, eating holes in them and bits out of the margin, and when it is ready to pass into the pupa state it goes into the empty pith places in old cut stems or twigs, and thence downwards to undergo its metamorphosis, which takes place in the following spring. I have received quantities of old cut portions of pruned Roses from Dumfriesshire, from which I have bred this species, and in these, like Taschenberg, I have found both larvæ and pupa, and the old cells appeared at least as if they were of the former year, and not having bred *M. bipunctata* from them is in favour of Taschenberg's view. However, it is a point on which no doubt ought to exist, and I suggest it to the observation of entomologists during the following season.

Cladius difformis, Parry.—The style of work of this species is to make small holes from the under-side through the leaf. The eggs are laid on the under-side, and the larvæ feed from there at once. The larva is dark green, and the perfect insect shining

FIG. 8.—ROSE STEM-BORING SAWFLY.

black except the feet. Curtis, writing in 1842, says that some twenty or thirty years previously it had been a rare insect, but was then well established in the gardens around London.

Tenthredo Zona, Klug.—Boisduval describes this species as occasionally found near Paris. I do not know if it has been met with in England. It attacks the leaves in much the same way as the last, living on the under-side, and making holes in them. When feeding the larva is stretched out, when in repose it is rolled up like a Planorbis. It is black, and bright yellow below. The perfect fly is black, with the abdomen partly yellow.

Emphytus rufocinctus, Klug.—Has the same habits and occasions much the same kind of damage to the leaves as the last, living on their under-side. It is also a French species, which is, so far as I know, not recorded in Britain.

Lyda inanita, d. Vill.—This species is well described by Professor Westwood in this journal, 1847, p. 684. He has called it the Rose caddice fly, from the curious cigar-like rolls, composed of leaves that it makes for its offspring. These are shown in the accompanying figure (fig. 9). It is rare in Britain. Andrew Murray.

ing, and by making layers and cuttings, and if we know why the bud joins to the stock, or the cutting sends out roots from the severed extremity, we shall work easily and successfully, for we shall know when and how to vary from directions which cannot possibly suit all circumstances.

THE MACHINERY AND ITS ACTION.

A plant is made up of minute cells or bladders, little bags of elastic membrane filled with a viscid

FIG. 9.—THE ROSE CADDICE.

fluid, called protoplasm, and plants grow by the subdivision of this protoplasm into two, three, or more new cells, each becoming clothed with its own coat or cell-wall. These new cells again divide into others, and so again and again, constantly pressing forwards and forming the lengthening shoot and the new growths between the wood and the bark that constitute the yearly increase in thickness alike of the Oak trunk or the stem of the Rose, and indeed of the larger proportion of plants in our own climate.

As long as this viscid fluid or protoplasm is active growth continues, or may continue, but presently the cells alter—some branch, some join end to end, so as to form long vessels, while some become thick and hard as those of the wood and bark. Various parts of the plant have each their own shape of cell; and after a time the protoplasm ceases to exist inside them, and in the absence of this active formative material they can no longer divide and make young ones.

But though the heart-wood, made up of cells no longer capable of division, and therefore is of no use in making cuttings, fluid is drawn up through the cells of the young wood in the outer part of the tree, and by the system of its circulation (too minute and elaborate to be entered on here) new growths are formed year by year between the wood and the bark, in what is called the "cambium region," and it is on this growth

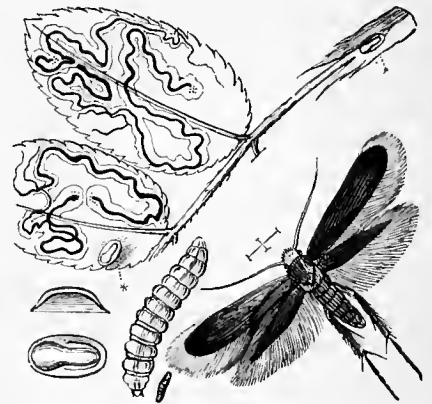

FIG. 10.—ROSE LEAF MINER.

AMATEUR GARDENING :
BUDDING.

IN feeding with their roots, as explained in previous numbers, and digesting with their leaves, plants prepare what is to form their growths, but how these growths are formed is worth considering.

The moisture drawn in by the roots flows up to the leaves, and evaporating more or less quickly as the weather is more or less warm, or the sky more or less bright, is partly converted into, partly brings with it, the materials to form and fill the cells of which the plant is built up.

On the proper formation of these cells depends our success in what is called "propagation," that is, the multiplication of our specimens by budding and graft-

between wood and bark that depends our success in matters of propagation.

BUDDING.

In the increase of specimens by budding it is the young cells forming the inside of the bark and the outside of the wood which unite by the action of the living fluid within them, to form one tissue. In ordinary Rose budding the season at which the operation is performed is selected as being that which is most favourable to this process; and all the steps of the process, the part of plant selected, the manipulation, and subsequent management, are devised with the intent of making the most of the growth of cells between the bark and the wood.

Take a healthy young Rose shoot, choose a well grown bud upon it, pass a sharp fine knife into the shoot about three-quarters of an inch below the bud, and drawing the knife upwards pare off a small shield-shaped morsel of bark with the bud, and the thinnest possible film of wood inside the bark, the knife being drawn out a little above the bud.

For the stock a healthy free-growing shoot should be chosen, a short cross-cut should be made with a sharp knife just through the bark, and another downwards from the centre of it from *a* to *b*, fig. 11; the upper angles of bark on each side of the stem of this T-shaped incision should be raised from the wood with the thin handle of the budding knife, and then

FIG. 11.—T-BUDDING. (SEE ALSO FIG. 12, *g*.)

(the thin film of wood inside the bark shield of the bud having been gently removed so as not to jerk out the growing point inside the bud), this shield holding the bud should be slipped, right way upwards, down the T-shaped incision as in *c*, fig. 11. The top of the bark shield, *c*, must be cut sharply across fig. *d*, so that it may fit cleanly and closely up to the severed bark at the top of the T; their severed cells must thus be in contact, and the shield with the bud closely fitted against the exposed wood of the stock. The flaps of the raised bark being put down again over the bark of the inserted bud, and the bud bound firmly in its place, but not too tightly, with bast or worsted, fig. 12 *g*, or whatever material may be preferred, the operation is complete.

THE PHILOSOPHY OF BUDDING.

The *modus operandi* of budding may be varied almost indefinitely, but the principle is always the same. A piece of growing bark is transplanted from its own wood to another piece, so that the two growths may unite into one living tissue. It may be useful to trace the process from the beginning.

Firstly, we take the time of year (July to September, with Roses) when the bark separates freely, because it is the presence of the sap forming all the

young cells between the bark and the wood that allows the separation to take place. If it did not "run," as it is called, it would be a sign that the young cells were not in action, and the surfaces that we tore and rent away from each other would not have their living coating in a state to unite. Also, buds about the centre of a shoot are often the best, as those at the base are apt to part with difficulty, and those at the top may not be sufficiently ripe.

We start the knife below the bud, that there may be clean edges, as the part where the knife comes out is necessarily frayed; it is best placed where it will presently be cut clean. When the incision is made as an inverted L, the knife is inserted above the bud, and the clean cut is made below. Amongst the many methods of budding the "reversed L" form is sometimes recommended where an excessive flow of sap or "gunning" might be expected to hurt the bud.

Scallop budding consists of paring off a small tongue-shaped bit of bark with the bud, and a thin film of wood, and placing it with the wood where a similar bit has been removed from the stock, fitting the bark either above (as with T budding), or at one side by a sharp cut. This form of budding is less troublesome, but also less certain, than T budding.

Annular budding, fig. 12 *f*, consists of removing a whole ring of bark to a similar exposed surface on the stock, a longitudinal slit allowing removal of the perfect ring. This is used with bark of considerable thickness, but requires some practice to manage nicely.

In some methods and with some plants it is thought best to leave the thin film of wood in the bark, but generally the principle of budding is when bark and wood are being separated naturally by the tide of new formation of tissue between them, so to separate and reunit them artificially that the process may continue.

So long as the edges are clean cut it does not matter how the cut is made. Some use a carpenter's gouge, and scoop off a piece of bark and a bud with great success. Others find it answer to use what is sometimes known as "Lymburn's method," which has been particularly recommended for Peaches, Plums, and Cherries, and which consists of cutting sharply round the piece of bark to be removed with the point of a knife and running it off with the nail, without any wood adhering. The common way, however, is probably the best, for the thin film of wood (which some budders think it will not to remove at all) should remain till all is ready for its insertion, and so the cells inside the bark are kept unexposed and moist till the very instant of placing on those of the stock; and herein lies the secret of successful budding.

If the two surfaces are placed together whilst still moist they will unite, as in animal life the two sides of a cut join together—the cells will grow together, new cells will form amongst them, and there will be a complete union; but if the surfaces are allowed to dry the cells will probably be killed, life will go out of them with the living fluid, which is as necessary to their growth as the blood in our own veins, and the bud "will not take." Here we have the reason of the speed sometimes so much dwelt on—it is only to avoid drying the surfaces, but there is no need of hurry—quiet work will give more likelihood of success, and especially avoid the risk (in hasty jerking out of the film of wood) of also jerking out the centre, the growing point, of the

bud. If this happens, though the bud may "take," it will not grow; it is as hopeless for increase as an empty egg-shell.

With regard to the stocks we use young or half ripened wood, for the same reasons that guide the choice of the bud; and because the vital action of plants is strongest near the leaves it is well to insert the new bud a little below a leaf rather than on a long bare stem.

The newly-placed bud depends on good feeding to make its growth; therefore, besides being placed just where the presence of a leaf keeps the current active, there should be several leaves beyond it on the branch of the stock to elaborate food, and the shoot should be "stopped" to encourage growth at the side-buds instead of at the tip. For the same reason a cloudy

FIG. 12.—ANNULAR BUDDING; *f*, T-BUD COMPLETED. (SEE FIG. 11).

day or morning or evening are preferable times for the performance of the operation to hot sunshine, in order that the bud should be not too rapidly dried to begin with.

The time of year varies with the plant to be budded; thus, July is suitable for Apples or Roses, August or September for Rhododendrons, the mark of the proper season being the formation of buds in the axils of the leaves of the current year. Unless the plants which furnish the bud and that used for the stock are nearly related junction will not take place, but how far the bud and stock act on each other is a question which is just in the province of the amateur to follow up at leisure.

AFTER-TREATMENT.

For previous and subsequent treatment of buds, it may be just mentioned that if they must be packed, the bits of shoots containing them will travel fairly in damp moss. After the operation the ties should be watched, lest the swelling growth should make a looser bandage requisite, and in the spring of the year after insertion the shoot of the stock on which the bud is placed should be shortened with a sharp clean cut to just above the point where the bud (which is now a strong young shoot of the newly inserted variety) takes its origin from the stem.

In grafts the process is very similar; in cuttings the whole of the plant powers (save those of reproduction) are brought into action. *O*.

PAUL & SON'S CHESHUNT ROSES.

MESSRS. PAUL & SON,

THE OLD NURSERIES, CHESHUNT, N.,

WILL BE PLEASED TO SEE ALL ROSE GROWERS,

TO INSPECT THE ROSES AT THEIR LONG
CELEBRATED NURSERIES.

The Rose Fields are well worth seeing, and the position occupied by the Flowers at the various Shows this year show that the Cultures, now continued through three generations, are maintained.

The Nurseries are One Mile from the Cheshunt Station of the Great Eastern Railway, where flies may be had—Two Miles from Waltham.

ADDRESS CAREFULLY, to avoid confusion of Firms—

PAUL & SON,

THE "OLD" NURSERIES, CHESHUNT, N.

NEW ENGLISH-RAISED SEEDLING ROSES.

MESSRS. BELL & SON,
THE NORWICH NURSERIES,

Are now executing orders for their TWO NEW ROSES, raised at their Nurseries, and described and announced below. They have been thoroughly tested here before being sent out, and can be recommended with confidence as really distinct novelties.

CLIMBING ROSE "CATHERINE BELL."

Very large flowers of a deep rose colour, the backs of the petals a delicate silvery pink, of exquisite shape and very fragrant. It is very free-flowering, and of vigorous climbing habit, making shoots 6 feet to 8 feet long in one season. Figured in *The Garden*, March 18, 1876.

"Your Rose Catherine Bell is both *belle et grande*."—Rev. Canon Reynolds Hole.

Good Flowering Plants, in Pots, 10s. 6d. each.

COLOURED PLATES ONE SHILLING EACH.

HYBRID TEA ROSE "MRS. OPIE."

Bright salmon-rose, tea-scented flowers, with shell-like petals, a most distinct and novel shade of colour among Tea Roses. It will form a charming companion to Madame Falcot, and will be as extensively cultivated as that variety when well known. In flower from May to November. Figured in the *Floral Magazine*.

Good Flowering Plants, in Pots 7s. 6d. each.

BELL AND SON, 10 & 11, EXCHANGE STREET, NORWICH.

ROSES  IN BLOOM.

WM. PAUL & SON

BEG TO ANNOUNCE THAT THE

COLLECTION of ROSES at the WALTHAM CROSS NURSERIES
IS NOW IN BLOOM.

Old and New Sorts, Show and Decorative Roses are alike Cultivated.

Admittance free on presentation of Address Card. Adjoining the "Waltham" Station, Great Eastern Railway, half an hour's ride from Liverpool Street or St. Pancras Stations.

WM. PAUL & SON,

(Successor to the late A. PAUL & SON—Established 1806)

WALTHAM CROSS.

ROSES.

CHARLES TURNER

Begs to call attention to his large
and varied

STOCK of ROSES, now in FULL BLOOM.

An Inspection is invited.

Roses in Pots are made a speciality at the Rose Nurseries, Fourteen First Prizes having been awarded to his collections during the last Spring, including the two Great Prizes of £25 each.

ROSES, in 7-inch pots, for Early Forcing, which include a fine collection of Teas, are 30s. to 42s. per dozen.

ROSES, in 4-inch pots, 18s. per dozen.

STANDARD and HALF STANDARD, ready for delivery in October, 21s. to 30s. per dozen.

DWARF STANDARDS, 12s. to 18s. per dozen.

DWARFS on MANETTI, 12s. per dozen.

The following New Varieties raised at the Royal Nurseries are highly recommended, and have received numerous Certificates and Prizes :—

MRS. BAKER (Turner), bright carmine.

OXONIAN (Turner), shaded rose, very large and globular.

J. S. MILL (Turner), bright red.

MISS HASSARD (Turner), beautiful pink, fine habit.

REV. J. B. CAMM (Turner), rosy pink.

ROYAL STANDARD (Turner), soft rose, very double.

The above six New varieties can now be supplied in pots, at 2s. each, Standards in the autumn.

A Descriptive CATALOGUE of the leading varieties may be had on application to

THE ROYAL NURSERIES, SLOUGH.

**THE NEW SEEDLING ROSE,
"QUEEN of BEDDERS"
(NOBLE).**

See Coloured Plate (after Mrs. Duffield), "*Gardeners' Chronicle*," May 5, 1877.

Perhaps the finest of all the English Seedling Roses of recent introduction. It is *par excellence* a really Bedding Rose in every sense of the word—requires no pegging down, support, or training of any kind, and is a continuous early and late bloomer.

First-class Certificate Royal Horticultural Society, August 2, 1876.

Its inflorescence may be imagined when it is stated that a plant 18 inches high had eighty-four buds and expanded flowers upon it on September 6, 1876.

A constant supply of buds was obtained from early June to November of that year—over five months.

Good Plants are now being sent out in strict rotation at 10s. 6d. each.

Coloured Plates 1s. each.

CHARLES NOBLE, BAGSHOT.

Established upwards of 70 years.

**THE ROSE NURSERIES,
HERTFORD.**

One of the earliest homes of the Rose is at Hertford, and where may be seen this season Thousands of Roses in splendid condition and flower, and

E. P. FRANCIS & Co.

RESPECTFULLY INVITE AN INSPECTION.

Frequent Trains by Great Eastern and Great Northern Railways run to Hertford, and the Nurseries are only a short distance from the Terminus.

Note the Address—

The Rose Nurseries, Hertford, Herts.

N.B. — CATALOGUES of ROSES, FRUIT TREES, and EVERGREENS, &c., gratis on application.

40,000 Roses in Pots.

WM. WOOD AND SON respectfully invite attention to their magnificent Tea-scented and other ROSES in Pots, in fine healthy plants, 12s. to 13s. per dozen, 100s. per 100.

Also extra fine Plants, established in 6-inch pots, for Conservatory or Greenhouse, at 30s. per dozen.

New ROSES for 1877, at 36s. per dozen.

WM. WOOD AND SON, The Nurseries, Maresfield, Uckfield, Sussex.

R O S E S,
CRANSTON'S NURSERIES,
KING'S ACRE, HEREFORD.

(ESTABLISHED 1875.)

THE LARGEST ROSE GARDENS
IN ENGLAND.

MESSRS. CRANSTON & Co.

Beg to announce that their ROSES (extending over many acres), are now in full bloom.

As considerable time will be required to inspect the whole of their Collection, Visitors to the Nurseries should take the morning trains arriving at Barr's Court, or Barton Stations, 2½ miles from the Nurseries, where conveyances are to be had.

Rose Blooms for Decoration supplied.

R O S E S.

Rosarians are recommended to buy their Roses of

EWING & CO.,

who grow them in an open position, on moderately rich soil resting on a naturally well drained subsoil, thereby securing vigorous growth and well ripened wood.

ROSES IN POTS.

Thirty Thousand Roses are also now grown annually by

EWING & CO.,

in Pots, and the very superior quality of their plants is now thoroughly recognised by their customers.

LISTS FREE.

THE ROYAL NORFOLK NURSERIES, EATON, near
NORWICH.

The Best Hardy Bedding Plant.
CLEMATIS JACKMANII.—Flowers rich purple, 4 inches across, and so profuse as to completely cover the bed. Begins to bloom in June, and continues until severe frost. It is perfectly hardy, and the stools improve annually. The only secret of success is a rich soil, to keep up free growth. Strong plants in pots, 12s. per dozen; extra strong plants, a year old, 18s. per dozen. Other sorts of Clematis and Climbers in great variety. Descriptive LIST on application.
RICHARD SMITH, Nurseryman, Worcester.

VANDA LOWII.—A magnificent specimen, 5 feet high, twenty-two leaves, strong break five leaves; bore two spikes of bloom last season, 7 to 8 feet long. Also a few plants of the magnificent new **HYBRID DENDROBIUM**, "Ainsworthii," shown in a great state of perfection at the late Manchester Exhibition: vide *Gardener's Chronicle*, June 9, 1876; and June 16, page 750. Prices on application to
GEORGE TOLL, 358, Stretford Road, Manchester.

SALES BY AUCTION.

Great Clearance Sale of Nursery Stock at the HAMMERSMITH NURSERY.

MR. J. C. STEVENS has received instructions from Messrs. Lee, to offer for SALE by AUCTION, on the Premises, at the Hammersmith Nurseries, Hammersmith, W., on TUESDAY, July 24, and following days, at half-past 12 o'clock precisely each day, the third and concluding portion of STOVE and GREENHOUSE PLANTS, together with the GREENHOUSES, PITS, BOILERS, &c., the land being required for building purposes. On view the day prior and mornings of Sale, and Catalogues had at the Nursery, and of Mr. J. C. STEVENS, Auctioneer, 38, King Street, Covent Garden, W.C.

Houghton Estate.

ANNUAL TIMBER SALE.—Twelve miles from Lynn, ten from Fakenham, and seven from Snettisham Railway Stations.

WILLIAM C. HOPKING is favoured with instructions from the Most Noble the Marquis of Cholmondeley, to SELL by AUCTION, on WEDNESDAY, July 25, 200 splendid OAK TIMBERS, many of which are from 30 to 40 feet in length, of great girth and very clean. 130 ASH TIMBERS, and 14 ELM TIMBERS, some of which are 40 feet in length. A large quantity of OAK WRONGS, about 20,000 HARDWOOD FAGGOTS, and two large STACKS of BARK, the produce of the entire fell for this season of 232 Oak Timbers. The Bark is secured in very good order, and is of the best quality.

The Auctioneer has particular pleasure in calling the attention of Timber Merchants and the purchasers of Bark to the above-described Sale, it being the finest fell of timber offered for Public Competition on the Estate for many years.

Sale to commence at 10.30 punctually, in the Park, close by the road leading from Bircham to Rudham.

A Conveyance will leave the Globe Hotel, King's Lynn, and Fakenham Station at 8.30 o'clock for the convenience of Purchasers.

Catalogues may be had a fortnight previous to the Sale on application to W. FREUER, Esq., Estate Agent, West Rudham, Brandon; or to the Auctioneer, Great Bircham, Lynn, Norfolk.

TO BE SOLD, on easy terms, a FLORIST and SEEDSMAN'S BUSINESS, with SMALL NURSERY. Good Jobbing connection. Excellent Shop and Premises. Long Lease. 2, Swiss Terrace, South Hampstead, N.W.

CHARLES EDWARD ELLIOTT, Honorary Treasurer and Secretary. Money Order Office, Ceramic Court, Crystal Palace.

THE IMPROVEMENT OF LANDED ESTATES, BY DRAINAGE, ENCLOSING, CLEARING, and the ERECTION OF FARM BUILDINGS and COTTAGES.

The Land, Loan and Enfranchisement Co. (Incorporated by Special Act of Parliament)

ADVANCES MONEY:

1st.—To the OWNERS of SETTLED and OTHER ESTATES, for the Erection of Farm Buildings and Cottages, and for the Drainage, Irrigation, Enclosing, Clearing and General Improvement of Landed Property in any part of the United Kingdom.

2d.—To the OWNERS of SETTLED ESTATES in ENGLAND, for the Erection or Completion of Mansions, Stables, and Outbuildings.

3d.—To LANDOWNERS generally, to enable them to subscribe for Shares in Companies for the Construction of Railways and Navigable Canals, which will beneficially affect their Estates.

4th.—To INCUMBENTS, for the Improvement of their Glebe Lands, by Drainage, and the Erection of Farm Buildings and Cottages.

5th.—To COPYHOLDERS, for the Enfranchisement of Copyhold Lands.

The amount borrowed, with the expenses, would be charged on the Estate benefited, and repaid by a rent-charge, terminating in twenty-five years. No Investigation of the Landowner's Title is necessary. Forms of application, and all further particulars may be obtained of Messrs. RAWLENCE and SQUAREY, 22, Great George Street, Westminster, S.W., and Salisbury; of Messrs. ASHURST, MORRIS, CRISP, and CO., 6, Old Jewry, London, E.C.; of Messrs. GILLESPIE and PATERSON, W.S., 81A, George Street, Edinburgh, Agents for the Company in Scotland; and at the Offices of the Company, as below.

T. PAIN, Managing Director. EDWIN GARROD, Secretary. Land, Loan, and Enfranchisement Company, 22, Great George Street, Westminster, S.W.

CRANSTON'S NURSERIES, KING'S ACRE, near HEREFORD.

Address—CRANSTON & CO.

**THE NEW SEEDLING ROSE,
 "QUEEN of BEDDERS"
 (NOBLE).**

See Coloured Plate (after Mrs. Duffield), "Gardeners' Chronicle," May 5, 1877.

Perhaps the finest of all the English Seedling Roses of recent introduction. It is *par excellence* a really Bedding Rose in every sense of the word—requires no pegging down, support, or training of any kind, and is a continuous early and late bloomer.

First-class Certificate Royal Horticultural Society, August 2, 1876.

Its inflorescence may be imagined when it is stated that a plant 18 inches high had eighty-four buds and expanded flowers upon it on September 6, 1876.

A constant supply of buds was obtained from early June to November of that year—over five months.

Good Plants are now being sent out in strict rotation at 10s. 6d. each.

Coloured Plates 1s. each.

CHARLES NOBLE, BAGSHOT.

B. S. WILLIAMS'

NEW AND CHOICE

FLOWER SEEDS FOR 1877.

SATURDAY, JULY 14, 1877.

THE FOLKLORE OF THE ROSE.

AMONG the many flowers round which in the lapse of centuries a popular history has accumulated, there is none which occupies a more prominent place than the Rose. Whether we look to the position which it occupies in the poetry of almost all lands, to its historical, literary, and legendary associations, to its individual popularity as a garden flower, or to the attention which it has attracted among horticulturists for these many years past, we shall find the Rose pre-eminent among flowers. In common with the Lily, the Violet, and one or two other favoured blossoms, the Rose seems to have become regarded as a synonym of a flower; and hence we find its name applied to plants of widely separated families, not only in our own tongue, but in that of many other countries. The poetical references to the Rose would occupy by themselves a volume of considerable bulk, while to trace out fully all its associations, to describe its varieties, in a word to monograph its history, would require many books, and such a task is hence obviously far beyond us on the present occasion. We will, however, briefly bring before our readers a few of the more interesting facts connected with the place occupied in history and legendary lore by the "Queen of Flowers."

It would probably be impossible to ascertain when the Rose was first recognised as the emblem of England, but it has certainly been associated with our country from a very early period, for Pliny, speaking of the name Albion, seems in doubt whether this name referred to our white cliffs or to the white Roses which abounded in the island: "*Albion insula sic dicta ab albis rupibus quas mare alluit, vel ob rosas albas quibus abundat.*" The popular idea that the white Rose was first adopted by the Yorkists during the civil war to which our flower lent its name, is not a correct one, in spite of the sanction which it receives from the "immortal bard." Dr. Brewer states that it was a hereditary cognisance of the house of York, and had been borne by them ever since the title was first created; while the red Rose was the accepted badge of Edmund, first Earl of Lancaster. The "rose noble," a gold coin first struck by Edward III. in 1334, bore upon one of its faces the figure of a Rose. It ceased to be coined during the reign of Henry V., but its name is not unfrequently met with in old writers. Later on we again find the white Rose employed as a political symbol. It was adopted by the Jacobins as an emblem of the Pretender, apparently because his adherents were obliged to help him secretly, or "under the rose." This last phrase, by the way, appears to date from classical times, when Cupid gave a Rose to Harpocrates, the God of Silence, as a bribe not to betray the amours of Venus. The Rose was subsequently suspended from and sculptured on the ceilings of dining-rooms, as a hint that sentiments uttered in the course of friendly gatherings should not be repeated elsewhere. Newton, in 1587, speaks of the hanging of Roses over the tables as a common country custom in parlours and dining-rooms; and Peacham, in 1638, says that they were painted in position as well in England as in the Low Countries. The plaster ornaments which are

often seen in the centre of our modern ceilings are still called Roses.

The Rose held an important place in mediæval ecclesiastical history, the blessing of the "golden Rose" upon mid-Lent Sunday being a ceremony which was confined to Rome itself, the reigning Pope being the officiant upon the occasion. Different Popes are credited with the introduction of this ceremony, the dates at which it was instituted being given by different authors as ranging between 1048 and 1247. The former is the date assigned by Calmet in his *Vérification des Dates*, who states that the ceremony was instituted by Leo X. There is an old mosaic in the church of St. Susan at Rome, in which Charlemagne is represented kneeling and receiving from St. Peter a standard covered with Roses. The Rose, having been blessed by the Pope, was subsequently sent by him as a mark of especial favour, usually to some king or queen; it was not, however, exclusively bestowed upon persons of high rank, and the present Pope has upon at least one occasion sent the golden Rose to a singer distinguished for her personal excellence. Pope Julius II. sent, in 1510, a golden Rose, duly blessed and perfumed, to Henry VIII., to whom it was presented by the hands of Archbishop Warham. Besides Mid-Lent Sunday, another one, that within the octave of the Ascension, is associated at Rome with the Rose under the title *Dominica in rosis*; this has reference to a twelfth century tradition, which states that, during a sermon of the then Pope in the church of St. Maria Rotunda, a shower of Roses fell from the roof.

If we stray into the field of ecclesiastical tradition, we shall find the Rose a prominent object. Roses and Lilies were the flowers found in the tomb of Mary after her assumption into heaven; Roscs, again, were the blossoms sent by St. Dorothy from the heavenly garden, in response to the challenge of Theophilus; Roses replaced the alms of Elizabeth of Hungary when her apron was rudely torn from her grasp by those who shared not her charitable zeal for the poor; and from the chaplet of Roses shown by the blessed Virgin to St. Dominic the popular Catholic devotion known as "the rosary" takes its name. "*Rosa mystica*" is one of the titles applied to Mary in the Litany of Loretto; and it was probably some vague reminiscence of ecclesiastical association which induced Lord Beaconsfield to represent (in his novel, *Lothair*) the Rose of Jericho as figuring in a Roman religious procession. It is unnecessary to state that the insignificant Crucifer to which this name is usually applied would be quite unfitting for employment on such an occasion.

Ecclesiastical tradition and secular history are agreed as to the institution of the *Rosière* in France by St. Médard, Bishop of Noyon, who in French weather-lore—and indeed throughout Europe—fills the position which we enlightened Britons still popularly give to St. Swithin—

"Quand il pleut pour le Saint Médard,
Il pleut quarante jours plus tard."

St. Médard was born at Salency, not very far from Noyon, and some time before his death, which took place in 545, he charged his family estate with a sum of money which was to be given with a crown of Roses to the most virtuous girl of that village. Until the time of the French Revolution, this ceremony, which was attended with much religious observance, and partook of the nature of a *fête*, was annually observed upon the 8th of June (the feast of St. Médard), and after a brief cessation was revived again in 1872, and has continued down to the present time. It has, however, undergone certain modifications, and the *Rosière* now receives 300 francs, half of which sum is given by the municipal council.

Nor is this the only occasion upon which the Rose figures in the history of France. In 1227 a custom called the tribute of Roses (*la baillée*

Per packet—s. d.

CALCEOLARIA, Williams' Superb Strain, 5s., 3s. 6d., 2s. 6d., and 1 6

From Capt. COSENS, Aberystwith, May 13, 1877.

"The Calceolarias, from the seed Capt. Cosens had from Mr. Williams last year, have been greatly admired—they leave nothing more to be desired."

PRIMULA, Williams' Superb Strain, Red, White, or Mixed 5s., 3s. 6d., 2s. 6d. and 1 6

PRIMULA SINENSIS FIMBRIATA COCCINEA (new), colour brilliant scarlet with bright sulphur eye, exquisitely fringed and of great substance 5 0

From Mr. F. DENNING, Gardener to J. Fenton, Esq., Yardsley, February 26, 1877.

"Dear Sir,—I may inform you that at the Birmingham Chrysanthemum Flower Show, held last November, I took the 1st prize, with twelve Primulas, six red and six white, in the Gentlemen's Gardeners' Class, with seeds supplied by you."

CINERARIA, Weatherill's Extra Choice Strain, 5s., 3s. 6d., 2s. 6d., and 1 6

From Mr. J. WEST, Gardener, Cheadon Park, May 21, 1877.

"Sir,—Your strain of Cinerarias, which have now been in bloom some time, have been and are now the admiration of all that have seen them, and are considered by gardeners to be the best ever seen in this neighbourhood. Habit very dwarf and compact, quite equal to the drawing in your catalogue."

CYCLAMEN PERSICUM GIGANTEUM (new) 2s. 6d. and 5 0

VICTORIA and PARADISE NURSERIES, Upper Holloway, London, N.

aux Roses) was instituted at Poitiers under the following circumstances. Parliament was convoked there early in May to decide upon an important matter. The Vidame de Bergerac, who had been married three times, had left seven children of each union, and it was necessary to decide whether the children of the first marriage should share his property equally with the younger branches, a point upon which laws and customs were not in accord. The Count Philibert de la Marche, to whom the report of the case had been entrusted, pleaded the cause of the orphans so successfully that his views were adopted by the magistrates, and the Regent, Queen Blanche of Castille, to perpetuate the remembrance of the day, and to remind the young peers how the most tender feelings should be turned to the advantage of justice, ordered that they should each year present to the Parliament a tribute of Roses. This custom was carried on up to 1589, the tribute being presented by the youngest peer of France; but in that year the League, no longer considering the Parliament as a court of Peers, abolished the custom, which has never been revived. *B. M.*

(To be continued.)

THE COLORADO BEETLE.

THE Dublin correspondent of the *Daily News* telegraphed to that journal on Tuesday last, that the unwelcome *Doryphora* made its appearance the previous day on the Dublin quay. The specimen discovered is said to have been a large one, and was found crawling on a rope close to the Liverpool docks. Confirmation of this report has not been forthcoming—indeed it has since been stated that the insect found in Dublin was not the Colorado beetle, meanwhile every grower of Potatoes should keep a strict look-out for the dreaded enemy, and farmers and gardeners especially should instruct their employes to report at once the appearance of any insects on Potatoes with which they may not be familiar. The Colorado beetle may be easily identified. The perfect insect looks at first sight like a very large Lady-bird, or Lady-cow, as that pretty little insect is sometimes less poetically called, but the colour of the Lady-bird is red with black spots, that of the Colorado beetle pale brown, with ten black lines or stripes arranged longitudinally down its back. It is not the perfect insect that is the most destructive, but the long hunched-bodied spotted grub or larva, which feeds voraciously on the haulm. The eggs, the larva, and the perfect insect, should be destroyed as soon as discovered. The most effective remedy, as we have before stated, for the beetle, that has yet been discovered is Paris-green—a preparation of arsenic, and consequently a most dangerous poison.

The most convenient method of using the Paris-green is, we repeat, by means of a tin capable of holding about 8 gallons, made of a shape to rest easily on the back of the labourer, as a knapsack or Cassiobury fire-engine would do. To the lower end of the can are attached two indiarubber tubes, each terminating in a "sprinkler" like the rose of a watering-pot. There is a convenient lever at the bottom which presses the tubes and shuts off the outflow at will. When about to be used "two bucketfuls of water are first poured into the can, then three tablespoonfuls of good green well mixed with another half-bucketful of water, and strained through a funnel-shaped strainer, which prevents the larger particles of the green from getting into the can and clogging up the sprinklers. Five to 8 acres a day can be sprinkled by one man, and from 1 to 1½ lb. of good green, according to the size of the plant, will suffice to the acre. . . . The walking serves to keep the green well shaken, and the flow of liquid is regulated at will by a pressure

of the fingers at the junction of the tubes with the metallic nozzles." It may not be amiss to suggest the absolute necessity of using the can and other implements employed in distributing the Paris-green for no other purpose whatever, and to insist rigorously on thorough cleanliness on the part of the workman when his work is done.

New Garden Plants.

CYPRIPEDIUM ALBO-PURPUREUM, *n. hybr.**

This is a hybrid raised from *Cyripedium Dominyanum* and *Schlimii*, the latter being the mother: hence it is a very great curiosity, the father parent being itself a mule. At first sight I looked for the anthers. They are exceedingly small in proportion to the other parts of the column, and have very little pollen, looking exceedingly flaccid. It is much to be desired that Messrs. Veitch may see whether this pollen has still the power of impregnation. I scarcely believe it, but a few granules might prove capable of doing their duty, and the offspring would be even far more interesting, being the nephew of a mule grandfather.

The flower is even a good deal larger than that of lovely *C. Sedeni*. It is whitish, with purplish on the borders of the lip, and many spots of same colour under it. The spots on the inflexed lateral lobes which nearly cover the mouth of the sac are much darker, and make a nice impression, since those lobes are ivory-white. The sepals have a slight purplish tinge on their borders. The petals are totally purplish and twisted, hanging down and exceeding much the length of the lip. The staminodium is light purplish, and adorned on each side with many bristles. All places where such a flower bears hairs, as the bases of petals and the sac of the lip internally abound with an unusual richness of hairs. I believe it is Mr. Seden's work, since I have to thank for it Messrs. Veitch. *H. G. Rehb. f.*

CYPRIPEDIUM PARISHII, *Rehb. f.*

I have just obtained a small flower of this well known plant with a black labellum and unusually dark petals. It has flowered on a spike with small normal flowers, where it is peculiar by an abortive stigma which I never saw before. I have to thank my excellent correspondent, our highly valued orchidist, Mr. Day, for this great curiosity. *H. G. Rehb. f.*

DENDROBIUM ARACHNOSTACHYUM, *Rehb. f.*,
supra, 334, vol. vii.

A fresh spike, kindly sent by Messrs. Veitch, proves this species to have light green flowers with internal decoration of the finest violet. The front of the column is totally violet; the lip, of a more yellowish tint, when compared to the sepals and petals, has the three longitudinal keels and the lateral veins of side lobes violet. Let me add that these are indeed green spiders, so that nobody needs being offended by the name. *H. G. Rehb. f.*

MASDEVALLIA (AMANDÆ) LEHMANNI, *n. sp.†*

This is a very nice *Masdevallia*, more florid than its ally, *Masdevallia polysticta*, with yellow-orange flowers, rounded membranous bracts, and peduncle a span high, longer than the oblong acute long-stalked leaves. A basketful of such inflorescences would be a novel aspect for Orchidists who are desirous of being excited by new impressions. It stands nearest *M. tridens*, *Rehb. f.*, was discovered in Ecuador by Mr. Lehmann, who sent many good Ecuadorian things (up to *Selenipedium Wallisii*!) to Mr. Low. Mr. Lehmann's name gives me the hope of his being my compatriot. There is, however, a strong indication of his having been in contact with English. Not because he sent a very beautiful collection of dried specimens—specimens, indeed, not scraps!—of Ecuadorian Orchids to Mr. Low for me. No, no! I am sorry to say *ce temps n'est plus*—collecting specimens is no more the general custom of English collectors, as in the glorious days of both the Lobbs, Purdie, the Cunninghams, and Gardner. No! It would seem that the English do not acknowledge a plant to be a specimen unless it be glued down. I

* *Cyripedium albo-purpureum*, *n. hybr.* (*Dominyanum* × *Schlimii*).—Aff. *Cyp. Dominyano* et *Schlimii*: sepalis summo oblongo acuto; sepalis inferioribus subaequalibus, labellum paulisper superante; tepalis linearibus tortis margine levibus, disco furfuraceis; labelli sacco oblongo acuto antice retuso; lobis lateralibus inflexis rotundatis, implicitis, staminodii transverso postice emarginato, antice tridentato; lateribus ciliato. Flores albi, purpureo aspersi.—*Selenipedium albo-purpureum* (*Dominyanum*—*Schlimii*).

† *Masdevallia (Amandæ) Lehmanni*, *n. sp.* *H. G. Rehb. f.*—Aff. *M. tridentis*, *Rehb. f.* Folis longe petiolatis cuneato oblongis acutis trinerviis pedunculo apice racemoso, bracteis semiovatis obtuse acutis cucullatis ovaris subaequalibus, ovaris crispis triteris; sepalis summo oblongo, sepalis lateralibus oblongo-ligulatis, omnibus in caudis æquilongis extensis, margine inferiori aspero ciliolato mucriculatis, tepalis oblongis acutis, lateribus serrulatis, labello ligulato ante apicem contracto, obtuse acuto; columna clavata acuta. Flores flavi semiplicares.—Ecuador, Lehmann! (ded. amic. St. Low).

have obtained splendid specimens glued down abroad on the most miserable grey blotting paper. I could not help thinking of the old General who declared a mantle was a useful thing for a soldier, provided it was neatly rolled on his back. After all it is much better to obtain a glued, or fastened specimen, than none at all, and I recommend myself to Mr. Lehmann for more such niceties by dedicating to him most thankfully this lovely *Masdevallia*. *H. G. Rehb. f.*

ALOE (PACHIDENDRON) PLATYLEPIS, *Baker, n. sp.**

Stem simple, attaining in the specimen examined a length of a yard below the rosette of leaves, and a diameter of 2—3 inches. Leaves 30—40 in a close rosette, extending over a length upon the stem of 1½—2 feet, ensiform, 1½—2 feet long, 2½—3 inches broad at the base, narrowed gradually to a long, acuminate point, unspotted, slightly glaucous, channelled down the face, broadly rounded on the back, ½ inch thick in the middle, the prickles deltoid, spreading, furnished with a minute horny tip, those at the base of the leaf about ½ inch, and the upper ones about ¼ inch long. Raceme dense, 6 or 8 inches long, 4 inches in diameter when fully expanded; bracts deltoid, ½ inch long and broad; pedicels erectopate, the lower ones as long as the bract. Perianth cylindrical, 12—13 lines long, pale scarlet or yellow, tipped and striped with green, the campanulate tube about ½ inch long, the ligulate permanently imbricating segments about an inch long. Six stamens all decidedly longer than the perianth; filaments pale greenish-yellow; anther oblong, ¼ inch long; pollen scarlet. Style exerted half an inch from the perianth.

ALOE (PACHIDENDRON) CHLOROLEUCA, *Baker, n. sp.†*

Stem simple, attaining in the specimen examined a length of one yard, and a diameter of 3—4 inches below the rosette of leaves. Leaves 30—40 in a dense rosette, ensiform, 2—2½ feet long, 2 inches broad at the base, narrowed gradually to an acuminate point, plain green, without any spots or bands; the upper half of the face rather channelled, the centre half an inch thick, the back rounded, the prickles crowded (in the lower part of the leaf five or six to an inch), deltoid cuspidate, ⅓—½ inch long, the upper ones especially upcurved. Raceme dense, nearly a foot long, 3½ inches in diameter when expanded; bracts lanceolate-deltoid, ⅓—½ inch long; pedicels erectopate, just equalling the bracts. Perianth tubular, straight, 12—13 lines long, a pale yellowish-white; tube campanulate; segments ligulate, keeled with green. All the six stamens exerted from the perianth a length of ¼—⅓ inch; filaments lemon-yellow; anthers yellow, oblong, ⅓ inch long, pollen bright orange. Style as long as the stamens. Closely allied to *A. platylepis*, from which it differs mainly by its denser, longer, narrower leaves, longer raceme, and differently shaped bracts.

There are two Aloes of the Pachidendron group, which we have had for some time in the Kew collection, ranged whilst the flowers remained unknown under *A. Salmodyckiana*, from which in habit and leaf they present no material character of difference. This spring my attention was called to them in a flowering state by my colleague, Mr. N. E. Brown, and we both agreed that they ought to be considered as distinct species. There is a good figure and description of *A. Salmodyckiana* in *Salm-Dyck's* monograph of Aloe, under section 27, fig. 1. It has a bright red flower, 1½ inch long, with a pedicel nearly as long as the perianth and twice as long as the oblong-rhomboid spatulate bract. No doubt both of them are Cape plants, but we do not know their complete history in detail. Many specimens of the three species may be seen at the present time growing side by side in the Succulent-house at Kew. *J. G. Baker.*

GASTERIA COLUBRINA, *N. E. Br.*

Plant about 15 inches high, with a spread of 18 inches or more. Leaves spreading; in young plants distichous, or sub-spirally distichous, ligulate, straight, 6—8 inches long, 1—1½ inch broad at base, 4—6 lines thick, flat or very slightly convex above, convex beneath, not truncate on one side, apex obtuse, shortly cuspidate, the edges cartilaginous margined and rough to the touch at the apex, but towards the base becoming obsolete tuberculate. As the plant gets older the leaves gradually become multifarious, and much longer and of a different shape, being in an adult plant 9—14 inches long, 1½ inch broad, 3—4 lines thick, acinaciform, straight or slightly sal-

* *Aloe (Pachidendron) platylepis*, *Baker, n. sp.*—Caulis protracto simpliciter; foliis 30—40 laxe rosulatis ensiformibus acuminatis bipedalibus leviter glaucoscentibus immaculatis, dentibus parvis deltoidibus; racemo simplici dense semipedali; bracteis latis deltoidibus, pedicellis bracteis æquilongis; perianthii subpollicaris, pallide scarlatini vel lutei tubo brevi campanulato, segmentis ligulatis; antheris omnibus exsertis; stylo longe protruso.

† *Aloe (Pachidendron) chloroleuca*, *Baker, n. sp.*—Caulis protracto simplici; foliis 30—40 dense rosulatis ensiformibus acuminatis 2—2½ pedibus viridibus immaculatis, dentibus parvis deltoidibus; racemo dense subpedali, bracteis lanceolato-deltoidibus, pedicellis bracteis æquilongis; perianthii subpollicaris luteo-albidi tubo brevi campanulato, segmentis ligulatis viridi vittatis; antheris omnibus exsertis; stylo longe protruso.

cate, sometimes a little twisted, very concave above from the base up to about 1½ inch below the obtuse cuspidate apex, which latter ¼ inch is flat or slightly convex, convex beneath, one side truncate from a unilateral carina, which extends from the base to the apex, and there forming the margin, the true margin disappearing before reaching the apex, one margin and apical third of the carina cartilaginous margined, and slightly rough to the touch, the other margin and middle part of the carina with slightly elevated cartilaginous tubercles. Both forms of leaf smooth, minutely white punctate under a lens, dark green irregularly mottled and banded with oval, more or less confluent pale green spots, which towards the base are much more elongate. Flowering stem 4 feet or more high, erect, branching just below the middle (if simple then usually much shorter), terete with the basal fourth compressed and sharply two-edged, dark green tinged with purplish upwards, terminal parts pale coral-red, everywhere covered with a glaucous meal, floriferous from about the middle, the racemes rather lax, bracts acuminate, as long as the pedicels (3 lines) in the uppermost, and twice as long (7 lines) in the lowermost flowers; pedicels 3-4 lines long; flowers 7½ lines long, curved, the globose inflated lower part 3½ lines thick, glaucous, basal part pale coral-red shading into very pale greenish white towards the lobes, each lobe with a broad green central stripe.

A native of the Cape of Good Hope; sent by Mr. Bolus to the Royal Gardens, Kew, where it flowered early in May, 1876, and has lately flowered again. As a species it is perhaps nearer to *G. dictyodes* of Salm-Dyck's Monograph, § 29, f. 4, than to any other published species, but the leaves are very much more concave, with larger and fewer spots, and the perianth is more inflated. When out of flower it has much the look of *G. acinacifolia*, but the short perianth at once removes it from the section to which that species belongs, and places it in the group *Breviflora*; it is also allied to *G. Boviana*, *G. maculata*, and *G. pulchra*, from all of which it is at once distinguished by its very concave, differently-shaped leaves. *N. E. Brown, Kew.*

THE FRUITING OF THE HOLLY.

THE paper read by Mr. M'Nab at the June meeting of the Botanical Society of Edinburgh (*Gardeners' Chronicle*, June 23, p. 782) is incorrect and very amusingly illustrates the adage that warns the man who wants a thing done to do it himself. Mr. M'Nab is too experienced and careful an observer to be allowed to remain in error as to the floral characters of Hollies, and he has but to look about him even now to discover that the list supplied to him by Mr. Johnston, of the Lawson Company, is in several particulars wrong. As regards the occurrence of hermaphrodite flowers, a plantation of common seedling *Ilex* will supply many examples. During the recent flowering season I examined about 200 fine young plants raised from berries sown in 1859, and I found very many flowers in which both sexes were perfectly developed, and in my collection of over seventy named varieties I noted that *laurifolia*, *lutea*, *Smithiana*, and *Silver Queen* produced a few hermaphrodite flowers, although all except one of these—*i.e.*, *lutea*—are to be regarded as males, and therefore not "fruit-bearing Hollies." There are two named varieties that claim consideration before all others in the study of the sexual characters of *Ilex Aquifolium*, and I respectfully direct Mr. M'Nab's attention to them. *Laurifolia* is entered in Mr. Johnston's list as a fruit-bearer, but it never produces fruit. It is the most floriferous of all Hollies, and bears flowers so freely as to present a really splendid appearance when at its best. In respect of beauty, when in flower it may be compared with *Acrophyllum venosum*, and its flowers are so fragrant that one old plant will perfume a large garden as effectually as the most fragrant *Crataegus*. For purposes of comparison, *laurifolia* may be regarded as a typical male. On the other hand *femina*, not entered in Mr. Johnston's list, is a typical female, for the flowers are all stigmatic, and the plant bears berries more profusely than any other of the garden Hollies.

Another mistake of Mr. Johnston's is entering *Shepherdii* as a male. Any one who will examine established plants of this variety now will probably find a few berries on them. It does not fruit freely, but plants that have not yet grown to the height of a foot will show a few berries, and the flowers are invariably females.

The most conspicuously fruitful of the named Hollies are *femina*, *lutea*, *flava*, *balearica*, and

selected female plants of the typical *Aquifolium*. I cannot at this busy time enter into particulars as I would wish, but I present a short list that may be useful:—

<i>Male-flowering Hollies.</i>								
ferox or Hedgehog Gold, few spined longiflora aurea Smithiana	Silver Queen doningtonensis heterophylla laurifolia							
<i>Female-flowering Hollies.</i>								
lutea Scotica Shepherdii Golden Queen femina	maderensis platyphylla glabra flava balearica							
<i>Hermaphrodite-flowering Hollies (producing Hermaphrodite Flowers Occasionally).</i>								
Smithiana Silver Queen heterophylla laurifolia	<table border="0"> <tr> <td style="font-size: 2em; vertical-align: middle;">{</td> <td style="vertical-align: middle;">Male flowers predominanting, berries rarely or never produced</td> <td style="vertical-align: middle;">}</td> <td style="vertical-align: middle;">lutea flava</td> <td style="font-size: 2em; vertical-align: middle;">{</td> <td style="vertical-align: middle;">Female flowers predominanting, berries plentifully produced</td> <td style="font-size: 2em; vertical-align: middle;">}</td> </tr> </table>	{	Male flowers predominanting, berries rarely or never produced	}	lutea flava	{	Female flowers predominanting, berries plentifully produced	}

Shirley Hibberd, Stoke Newington.

POTATOS AT CHISWICK.

I HAVE made a careful examination of all the Potatos at Chiswick, but it would be premature to attempt any description of the general effects of the disease at present. According to my estimate the Potatos named *Excelsior* and *Alpha* are by far the worst, so bad are these that it is probable after the lapse of a week or two they will have totally disappeared; after these for badness of disease I estimate *Hardy's Glory* and *Early Gem*, then *American late Rose* and *Long Red*. None of these have been treated by me with *Salus*; all six, especially the two first, which are prostrate, are notably attacked by the secondary condition (or resting-spore state) of the disease. On all six the *Peronospora* may be seen in small quantities.

As for the remainder of the Chiswick Potatos, they present so many diverse aspects of growth, habit, and health, that it is impossible to speak of them in a short letter. Many of the sets have totally perished, others have withered, and present brown and dry, and sometimes ill-grown and rotten haulm. As for the *Potato fuogus* proper, last Monday I could see very little indeed of it. What it may be after the lapse of a week or a fortnight I cannot venture to suggest. Neither is it easy at present to compare the plants treated by me with those not treated, for at present the *Peronospora* in its typical state is almost absent.

1. In the open there are fifty *York Regents* planted by me, twenty-four cut and twenty-six uncut, these all up and well; this *Potato*, under ordinary circumstances, is a very uncertain plant. Amongst the trees, where *York Regents* are again planted, there is only one case of doubtful disease amongst forty-three whole tubers, and out of thirty-nine cut tubers three have disappeared, and one is withered.

2. Coming now to *Striped Don*, a *Potato* which has a similar habit of growth with the last, out of the twenty-six uncut tubers in the open all are up and well, and out of the twenty-five cut three have perished. Under the trees the same *Potato* shows a loss of four plants only out of eighty-five.

3. *American Early Rose*.—This is an uncommonly bad *Potato* for taking the disease. Fifty plants were set in the open: of these four have perished, and fifteen are ill-grown. Amongst the trees seventy sets were planted; of these eight have not grown, and seven are ill-grown; the latter in every case I hope to recover.

4. *Breece's Prolific*.—This *Potato* has a very bad character, like the last, but in the open all the twenty-six uncut tubers are up and well; amongst the twenty-four cut only two have not grown. Amongst the trees, out of seventy-nine plants cut and uncut, all are good except four, which appear not to have grown.

5. *Paterson's Victoria*.—This is a *Potato* of the very first class; out of fifty plants in the open only two have failed to grow, all the rest are up and healthy. Of the eighty-nine plants amongst the trees, cut and uncut, nine have perished or have not grown.

6. *Lapstone*.—According to my estimate a very bad *Potato* for falling a prey to the disease: in the open fifteen out of fifty plants have vanished, but my *Salus* was exhausted when I reached the last sets in the open, so that the last mentioned were virtually not treated by me. Amongst the trees out of fifty-seven whole tubers two only have vanished, out of thirty-three cut twelve have disappeared. As far as my experience

goes cut tubers are commonly under a disadvantage when subjected to such extremes of cold, heat, and drought as we have had this season. At present I have not seen the *Peronospora* on the above plants; the next few weeks will prove whether my method of growing will have any decided effect on the attacks of *Potato-murrain*.

Elsewhere at Chiswick the failures of growth are in some instances very much worse than anything in my lot; for instance, *American Late Rose* in a row of seventy-three plants, thirty-seven have perished, and in the twelfth row from the corner amongst the trees thirty sets have perished out of about sixty or seventy; in row 6, twenty-eight have failed, and many are ill-grown; at the same time it must be confessed many rows are in apparently vigorous health both in the open and amongst the trees.

But as I said at first, it is premature to discuss the condition of all the Potatos at Chiswick at present, as the next few days may work some surprising changes. What is just now wanted is a good plainly-written label at the end of each row. Many rows are, unfortunately, without labels. *W. G. Smith.*

GREENHOUSE PLANTS.

THEIR CULTURE AND MANAGEMENT.

TRACHELOSPERMUM (RHYNCHOSPERMUM) JASMINOIDES.—In this we have a climbing plant of moderate growth, alike suitable for a trained pot specimen or for clothing a pillar or rafter, where the space to be covered is not too large; for although, in common with almost all other plants indigenous to China, it is a free grower, yet it does not attain the size of many climbing subjects. From the locality in which it is found, Shanghai, it is very nearly hardy in this country, succeeding on a sheltered wall, with a little protection, in the south of the kingdom: yet it is a plant that will thrive under a very considerable range of temperature, and will do equally as well in a cool stove, or intermediate heat, as it will in a greenhouse; but, of course, the progress made, in growth especially, during the early stages, from a small state upwards, is much quicker when it is subject to heat than when treated cooler. It will bear forcing: its white fragrant Jasmine-like flowers are produced in profusion from the ripened growth of the preceding summer. The shoots are of a semi-twining habit, and when the plant is in vigorous health will extend to considerable length in a single season, particularly if submitted to a warm humid atmosphere. The perfume is very agreeable, but not objectionably powerful; a small plant in flower will load the atmosphere of a large house. The ease with which it may be grown, even by those who have not had much practice in plant-growing, commends it to the inexperienced. When in a strong vigorous state each bunch contains a number of flowers, which open in succession, keeping the plant gay for several weeks consecutively.

It is well adapted for conservatory decoration, as the hard texture of the leaves renders it little subject to injury by keeping, whilst in flower, somewhat crowded amongst other things in a way that is often unavoidable in such structures. The somewhat short foot-stalk renders the flowers less servicable for using in a cut state than if longer; nevertheless, if not subjected to too much heat in opening, they are a useful addition for bouquets. As this *Rhynchospermum* can be kept for a long time in a small pot, and still have a fair appearance, yet nevertheless in reality be so stinted as to preclude the possibility of its growing freely, it is necessary to be careful in selecting young plants for growing on to see that their roots have not become too much matted, and the shoots of the thin, wiry character that indicates a condition to be avoided. One-year-old plants raised from cuttings the spring previous are much to be preferred to hard, older examples. These should be potted about the end of March, giving them a 2 or 3-inch shift according to the strength and quantity of their roots. It will succeed in either peat or loam, but I prefer the latter, as it will induce quicker growth, and in it the leaves have a darker, more healthy tint, which adds much to the general appearance, especially when in bloom, the dark glossy green *Myrtle*-like foliage forming a good background for the flowers. Let the soil be of a good fibrous description, using it from the first in a moderately lumpy state, as their roots are naturally strong. Add enough sand to keep it open, and drain the pots sufficiently. When the potting is

completed put half-a-dozen sticks 3 feet long in the new soil just inside the the rims of the pots. Round these train the shoots, at the same time pinching out the points to cause the production of an increased number of growths, for although really a climbing plant, and as such not necessarily requiring so much stopping as if it possessed a shrubby habit, still enough shoots should be formed to furnish the trellis which the plants will ultimately require. Place them in a house or pit, if such is available, where there is a night temperature of 50°, with a rise of 10° in the daytime. This will answer well for them, and so treated they will make much greater progress than if grown cooler; do not give much water at first until the roots have got possession of the new soil. Syringe the plants overhead every afternoon, and close the house at the same time; as solar heat increases the temperature they are subjected to may be proportionately raised. Very little shade will be required except for a few hours in the middle of the day in very bright weather, give them plenty of light, or the growth will become too much elongated and weak. The shoots as they grow must be kept regularly trained round the sticks, never bringing the points too low down, but allowing them to retain an upright position; a continuance of this treatment will be all that is needed through the summer, giving enough air in the middle of the day. By the middle of September discontinue syringing, and give more air with a drier atmosphere to discourage further progress and ripen up the growth.

Through the winter the plants will do in any house or pit where the temperature is kept at 35° in the night, giving just as much water to the soil as will keep the roots slightly moist. Again, in the spring, about the same time, remove into pots 4 or 5 inches larger, using similar soil. Uncoil the shoots from the sticks, and replace them with others longer and thicker that will support the increasing weight of the shoots, and train them regularly as before. It is not advisable to use a wire trellis until the season following; if the shoots are not sufficiently numerous, or there is an appearance of their extending too far, so as to be deficient near the base, again shorten the leaders. Treat through the spring and summer as in the preceding season, as before giving less water and more air in the autumn. I have said nothing about flowering during this summer, although the plant is such a free bloomer that it will have pushed its bunches from the base of the leaves at every joint made the preceding summer; but as the object will be to induce as much growth through the season as possible, the treatment when in flower should have been such as to keep them on growing.

Keep through the winter in a temperature such as in the last, and repeat again in the spring, giving a shift 3 or 4 inches larger, in proportion to the quantity of roots the plants have got. As before, take them off the sticks round which the shoots have been trained; they will now be large enough to cover a moderate-sized wire trellis, some 2 feet diameter by 2½ feet high above the pot; over this train the shoots regularly from the base to the top, and place them in a temperature similar to that they have each preceding spring been submitted to, if they are required early in bloom—if not they may be kept 5° cooler. When the flowers are about to commence expanding they can be moved to a conservatory, or any house where they will not be kept much above an ordinary greenhouse temperature, and receive a little shade from the sun which will prolong their flowering, after which, if they are not required to be grown on larger without delay, they may be treated through the summer similarly to the rest of the greenhouse hard-wooded stock; if, on the other hand, it is deemed desirable to grow them on to a larger size without loss of time, they should be submitted to a temperature such as hitherto used during the growing season. Be careful that the shoots as they extend do not get entwined round the wires of the trellis, or there will be some difficulty experienced in getting them loose to place upon a larger one, which they will require in the course of another year or two, when more root-room will be needed: thus treated the plants will last for many years.

When required for training up a pillar or rafter, it is well to grow them for a season in pots so as to get some strength in them before turning the roots out in a border: this should be well-drained and consist of good fibrous soil with enough sand and crocks, or charcoal, to keep it sweet and porous. Have the shoots from the first regularly trained, not allowing

them to become entangled, and as the space they are to fill gets covered the superfluous growth may be shortened back immediately they have done flowering each season. When the soil gets exhausted some of the surface may be removed every spring, and replaced by new, and when grown in this way, or in pits, manure-water will be a great assistance when the soil becomes filled with roots. There is a variegated form of this plant that will succeed by being treated in the above manner. It is scarcely so desirable a variety as the green-leaved sort.

Insects.—The stont nature of the leaves is such as not to suit the tastes of red-spider or aphides, although these insects will live upon the plant, but can be easily kept down by syringing. If scale makes its appearance it must be carefully removed by the use of sponge and brush. For mealy-bug, syringe and dip with a strong solution of insecticide in the winter when at rest. *T. Eaines.*

THE GENUS AGAVE.

(Continued from vol. vii., p. 622.)

SERIES I.—CORIACEO-CARNOSÆ.—Texture of the leaf rigid, not at all fleshy nor yielding to the touch when mature. End-spine large, hard and pungent.

Group IV. AMERICANÆ.—Edge of the leaf without any distinct horny border; teeth large, deltoideus-cuspidate, comparatively few in number.

We come now to the oldest and best-known group of the whole genus, which I will take in two subdivisions, first the species with oblong-spathulate leaves, like *Scolymus* and *potatorum*, secondly the species with oblanceolate leaves, like *flavescens* and *americana*. All the species of the *Scolymus* set of which the flowers are known have the *Euagave* inflorescence.

26. *A. (Euagave) Seemanniana*, Jacobi, Nachtrage, p. 29.—Acaulescent. Leaves 20 in a rosette 1—1½ foot broad, oblong-spathulate, 6—9 inches long, 3—3½ inches broad at the middle, narrowed to 2 inches above the dilated base, slightly glaucous, the face flat except close to the top, the base ½ inch thick, the centre ½ inch, the pungent dark brown end spine ½ inch long, the moderately close deltoideus-cuspidate teeth slightly curved upwards or downwards. Inflorescence unknown in cultivation. Flower-stem said by Dr. Seemann to be 6 feet high.

A native of Guatemala, brought to England by the late Dr. B. Seemann, about 1868, and distributed by Mr. Bull. It is closely allied to *Scolymus*, from which it differs in colour, and by its smaller teeth with margin not repand between them.

27. *A. (Euagave) Parryi*, Engelm. Notes, p. 23.—Acaulescent. Leaves oblong-spathulate, 10—12 inches long, 3—3½ inches broad at the middle, the robust pungent end spine 1 inch long, and running down the edge of the top of the leaf for an inch or more; the teeth ½—1 inch apart, deltoideus, only about ½ inch long, straight or slightly curved. Scape 8—12 feet high, bearing numerous large deltoideus erect bracts with scarios brown margins and sharp points. Panicle about 3 feet long and 1 foot broad, the stouter branches considerably flattened, ½ foot long; ultimate pedicels ½—¾ inch long. Perianth, including the ovary, above 2 inches long; tube 4—4½ lines long and broad; lobes ¾ inch long. Filaments inserted at the throat of the tube, more than twice as long as the lobes; anthers 10 lines long. Capsule oblong-trigonus, 1½ inch long; seeds punctate, ⅓ inch broad.

A native of Arizona and New Mexico, discovered by Lieut. Emory in 1846, and distributed in European gardens by Dr. Engelmann from seeds procured by Dr. Parry in 1868. Jacobi seems to have included it under his *A. crenata*, which appears to be a variety of *A. Scolymus*. I have not seen the present plant growing, but a full account of its characters and history will be found in Dr. Engelmann's paper.

28. *A. (Euagave) Wislizeni*, Engelm. Notes, p. 32; *A. scabra*, Salm-Dyck; Jacobi, Monogr., p. 88.—Acaulescent. Leaves about 30 in a dense rigid rosette, which is nuder 2 feet broad, oblong-spathulate, 3—3½ inches broad above the middle, narrowed to 2½ inches above the dilated base, where it is 1 inch thick, very glaucous, concave in the upper part, the hard pungent dark brown end spine 1 inch long and decurrent down the border a little, the base ½ inch, the centre ¾ inch thick, the dark purple deltoideus-cuspidate moderately close spines ½—¾ inch long, the margin not distinctly repand between them, those below the middle of the leaf smaller and curved downward. Scape 12 feet high. Panicle thyrsoid, its branches 3—6 inches long; ultimate pedicels 1—2 lines long. Perianth, including the ovary, 2½ inches long; tube and lobes equal in length, both taken together as

long as the ovary. Filaments inserted some distance down the tube, exerted ¾ inch beyond the lobes; anthers 10—10½ lines long. Capsule cylindrical-trigonus, 18—22 lines long, 7—8 lines in diameter; seeds under ¼ inch broad.

A native of the province of Chihuahua in Northern Mexico, where it was discovered by Dr. Wislizenus, in 1847. It is now widely spread in European gardens. I follow Dr. Engelmann, from whom my account of the inflorescence is taken, in rejecting Prince Salm-Dyck's name of *scabra* as inappropriate. It comes very near some of the forms of *Scolymus*.

29. *A. (Euagave) Scolymus*, Karwinsk.; Jacobi, Monogr., pp. 83 and 231; Baker, in Saund. Ref. Bot., t. 328 (fig. 3).—Acaulescent. Leaves 20—30 in a dense rosette 1½—3 feet broad, oblong-spathulate, 9—18 inches long, 3—6 inches broad above the middle, very glaucous, ¾—1 inch thick at the base, narrowed suddenly to a hard pungent end-spine an inch or more long, the teeth deltoideus-cuspidate, chestnut-brown, the upper ones ¼—¾ inch long, with the edge repand between, those of the lower half smaller and directed downwards. Scape 14—16 feet high, including the thyrsoid panicle, which is about 4 feet long by half as broad, furnished with copious lanceolate erect green bracts; branches few, with the flowers at the end in very dense clusters. Perianth greenish-yellow, 2½—3 inches long; ovary oblong-trigonus, above an inch long; lobes under an inch long, equalling the broadly funnel-shaped tube; filaments exerted ¾—1 inch beyond the lobes; anthers an inch long.

A native of Mexico, introduced into European gardens about 1830, and now very common. It has numerous named forms and varieties, of which the principal are *A. Schmittspahni*, Jacobi, Monogr., p. 83; *A. amana*, Lemaire; Jacobi, Monogr., pp. 84 and 234 (a smaller plant than typical *Scolymus*); *A. Verschaffeltii*, Lemaire, Ill. Hort., t. 564; Jacobi, Monogr., pp. 84 and 234; Baker, in Saund. Ref. Bot., t. 306; *A. Saundersii*, Hook. in Bot. Mag., t. 5493; Jacobi, Monogr., p. 223, tab. nost. (leaves about a foot long, teeth very large); *A. cucullata*, Lemaire, Jacobi, Monogr., p. 82 (leaves round-ovate, not more than 4—5 inches long, 3 inches broad); *A. crenata*, Jacobi, Monogr., p. 229; *A. Mescal*, K. Koch (less glaucous than the type), and *A. auriculata*, Hort. (leaves fifty or more in a rosette, thinner than in the type, moderately glaucous, with prickles ½ inch long). There are two good-coloured figures of different forms of the plant in the *Refugium*, and one in the *Botanical Magazine*.

30. *A. (Euagave) potatorum*, Zuccar.; Jacobi, Monogr., p. 78.—Acaulescent. Leaves about 20, arranged in a dense rosette 4—5 feet broad, oblong-spathulate, 2—2½ feet long, 7—9 inches broad above the middle, narrowed to 4—5 inches above the dilated base, where it is 2—3 inches thick, a dull, glaucous green, the face slightly concave, the hard, pungent end spine 1½—2 inches long, decurrent a little down the borders, the deltoideus cuspidate prickles ¼—¾ inch long, with the edge repand between them. Scape 12 feet high, including the thyrsoid panicle, which is 4—5 feet long. Perianth greenish-yellow, 3 inches long, including the ovary; segments about an inch long; filaments twice as long as the perianth-segments; anthers nearly an inch long.

A native of Mexico, introduced into Europe about 1830, and now widely spread in collections. Whether it be distinct specifically from *A. Scolymus* may be doubted. The principal difference is in size. The flowers are described by Jacobi, and there is an account in the *Revue Horticole* for 1875, p. 443, of a plant that flowered at Paris; but a figure is still a desideratum.

31. *A. ferax*, K. Koch; Jacobi, Monogr., p. 75.—Acaulescent. Leaves about 20 in a rosette, oblong-spathulate, 6—8 inches broad above the middle, narrowed to 4—5 inches above the dilated base, where it is 1½ inch thick, the face nearly flat, except at the top, a dull, slightly glaucous green, the hard, pungent point above an inch long, and decurrent a little down the borders, the margin repand between the large dark brown deltoideus cuspidate teeth, which are ¼—¾ inch long, and curved at the top, principally downwards. Inflorescence unknown.

A native of Mexico, first brought into notice in 1861. Intermediate between *A. Salmiana* and *A. Scolymus*. A plant which I saw in Mr. Peacock's collection called *A. Bonnetiana* comes very near this. *A. Guedeneyri*, Houlet, in *Revue Hort.* 1875, p. 465, judging from the description, must come near to *ferox*. It is said to have bright green leaves 2½ feet long, a stem 11—12 feet high, with numerous large reddish-violet bracts narrowed to a black point, a thyrsoid

panicle with twenty branches, yellowish-green flowers, and much exerted stamens. It flowered in the collection of M. Guedeney at Vesinet in 1875.

32. *A. Galotei*, Hort. — Acaulescent. Leaves 30–40 in a dense rosette 2–3 feet broad, oblong-spathulate, 1–1½ foot long, 4–6 inches broad above the middle, narrowed to 2–3 inches above the dilated base, where it is ¾–1 inch thick, the face flat or rather convex, green, hardly at all glaucous when mature, the centre ½ inch thick, the hard pungent end-spine ¾–1 inch long, and decurrent a little down the borders, the close deltoid cuspidate purplish-black prickles ½–¾ inch long, straight or slightly hooked. Inflorescence unknown.

This is a well-marked plant, which I do not find described, which I have seen under the name adopted both in the Saunders and Peacock collections. From the name I presume it to be a native of Mexico. It is marked in this subdivision by its green colour, and comparatively small teeth. *F. G. Baker.*

A VISIT TO THE WEST INDIA DOCKS.

To understand the wealth of the vegetable kingdom, and its importance in supplying the necessities of man, as well as the great part it plays in the commerce between this country and the various ports of the world, one need pay a visit to those great emporiums

by them in the history and sources of the several articles with which they are individually concerned. Thus in the tea warehouse we were treated to quite an accurate account of the nature of the Tea plant and its cultivation. The same may be said with regard to coffee: both these products being of a dry nature, the former contained in chests, and the latter in barrels or bags, the warehouses in which they are stored, and the ships from which they are unloaded, have a clean and trim appearance. This is not the case, however, with the sugar warehouse, the floors of which are saturated with the saccharine juice; and the quay, upon which, at the time of our visit, bags of Mauritius sugar were being landed, was literally swimming with molasses, so that one stuck at every footstep. Sugar is imported in various kinds of packages—the large hogsheads, often seen in grocers' shops, are the most unwieldy; they are, however, the most cleanly in appearance; for though upon landing their contents is more than apparent, owing to the sugar oozing through between the staves, they have not that soddened, dirty appearance that the bags have; for most of the Mauritius sugar comes in loosely made bags, formed with the leaves of *Pandanus utilis*, and the East Indian sugar in gunny bags woven from Jute: both of these become so thoroughly soaked with sugar that after being emptied of their contents they are sold to itinerant dealers, who boil them to extract the sugar and sel

in the same period gave 1,320,000 tons; and this last is supplied only by Germany, France, Russia and Poland, Austria, Hungary and Holland, against tropical countries far and wide, where the cane has been for years, and is still cultivated to a very considerable extent—as for instance, Cuba, British, Dutch and Danish West Indies, Brazil, China, Java, Matilla, Mauritius, Central America, Mexico, British India, and other countries.

If, as seems probable, the Beetroot will to a very large extent supplant, or at least compete with the cane in the production of sugar itself, an important commodity is still left to the cane, and that is in the production of the well-known spirit, rum, which is principally furnished by our own colonies, and for which there is always a large demand for supplying the navy. The official returns for the year ending December last, showed that no less than 10,476,503 gallons were imported, of which 5,024,419 gallons were entered for home consumption. These figures appear large, but a visit to the rum vaults at the West India Docks—where, of course, only a tithe of this quantity is stored—brings to our minds the reality of statistics. These vaults are fine specimens of ground brickwork, the arches being semicircular, and the piers square, broad at the base, and narrowing just before the spring of the arch. Looking diagonally across the vaults so that the arches intersect each other, a series apparently of equilateral arches are formed, which become more acute or pointed according to the change in the position of the person. The whole extent of these vaults is cleanly whitewashed, and notwithstanding the forest of casks, which however do not intrude themselves in the prevailing darkness, though, unfortunately, the odour of rum does, one can imagine themselves in the crypt of some immense Gothic cathedral. The only light obtained is from side windows, outside of which are fixed reflectors, and as the vaults are perhaps about 100 feet wide, it can be readily supposed that the centre is totally dark. The casks are arranged so that alleys or passages are left the whole length or width of the vault, and the ends of the casks form a wall on the right and left of these alleys, each cask being marked on this end with the rotation number and date of year when unloaded. These figures are marked with white paint, and when any particular cask is wanted, a reflector formed of a piece of common tin nailed on a piece of wood, is held up above the head so as to catch the light from the nearest window; the reflected light is thus thrown down on to the cask, and the number easily read. This plan, which is quite effectual, is adopted on the score of safety from fire, as no candle or lamp is allowed to be taken in. This plan of utilising reflected light is ingenious, and another ingenious contrivance is the instrument used for drawing samples from the various packages. Thus, for instance, if a sample of sugar be required from a large hogshead, a long iron instrument in the shape of an auger with a very deep groove and a stout wooden cross handle is driven through the side of the hogshead with a mallet, it is then twisted round till it reaches the centre of the hogshead, from which a sample of the sugar is withdrawn. These instruments are made sufficiently long to reach the centre of the package whether it be hogshead, cask, bag, or sack, so that it may be discovered whether the whole bulk of the article is of equal quality.

We spoke at the commencement of this article on the intelligence displayed by the men having charge of, or attending upon each floor. This was further illustrated by the interest shown by some of them in making collections of the several products which are brought into the docks. These specimens are mostly kept in glazed cupboards or drawers, thus forming a miniature commercial museum, and the men who have been instrumental in bringing them together, though unacquainted with their scientific names, talk learnedly about their commercial or native names, the countries of their growth, production and uses. Some years since a small museum was formed with these products so collected, and a room set apart—in connection with an already existing institute and library—for the proper exhibition of these specimens, glazed wall cases being provided at the expense of the directors of the Dock Company, and the collection arranged on a commercial system. Many of the specimens in this collection were very fine, and some even rare, having been obtained immediately on the arrival of the vessels in the docks. This little museum bid fair to become the nucleus around which a fine collection might have been gathered, but a "reorganisation

FIG. 3.—AGAVE SCOLYMUS VAR. SAUNDERSII.

of merchandise, the different docks—at which some of the noblest vessels discharge their valuable and varied cargoes, and ship others for transference to distant parts of the world. We may read of shiploads of this, that, or the other commodity being brought to this country, and perchance consumed by the population; we may also study tables of statistics, and express surprise at the mass of figures, but we have no idea of the actual bulk of any special product unless we happen to see a ship unloading, or, still better, pay a visit to the store buildings or warehouses of one of our great import docks.

These thoughts are brought to mind from what was seen in the course of an hour or two on a recent visit to the West India Docks. In the lofty warehouses rising from the landing quays of these extensive receptacles of foreign merchandise, are stowed property of almost fabulous value, and of course of great variety. One lofty block is perchance filled with tea, another with coffee, and another with sugar, each one of these articles has in itself a history interesting enough, but, moreover, one that has been often told, and therefore it would seem that nothing new can be learnt or said about them. On the contrary many scraps of information can be picked up at these places, from the men in charge of the different floors, to each of which is allotted a special commodity, and though these men are from outward appearance working men in the true sense of the word, it is remarkable the amount of intelligence displayed.

the bags to the paper makers. Whatever the nature of the package, or indeed of the cargo generally, they are all hauled up out of the hold of the vessel by cranes worked by hydraulic pressure; and insect life is also very abundant in some cargoes, the sugar-bags often teeming with cockroaches. One particular kind of sugar attracted our attention, occurring as it did in lumps or masses apparently closely compressed, each mass or package being between 2 and 3 feet long by 18 or 20 inches wide, and 1 foot thick—these were sown up in a kind of coarse sacking, and we learnt that this particular kind of sugar was shipped from Odessa; this of course dispelled the notion of it being cane sugar, and went to prove its origin to be the Beet, which was conclusive upon testing a sample, which left in the mouth a strong earthy or rooty taste, lasting a long time. This sugar is of a fairly light colour, and is, it seems, now brought into England in considerable quantities for the purpose of clarifying and crystallising. A sample of sugar from the same port, and from the same plant, crystallised before exportation, was also shown to us, and this, though in very small crystals, was as white as ordinary lump or loaf sugar, illustrating the degree of perfection attained in clarifying and crystallising sugar obtained from this source—a source, moreover, from whence we are fast obtaining our principal supplies, for statistics show that the produce of the Cane derived from all countries during the year 1876 amounted to 2,140,000 tons, while that from the Beet

of officers displaced those who had taken a lively interest in it, and the result is that the collection has not been touched, apparently not even for the purpose of dusting, since it was first arranged some years back. Consequently rival collections are formed, which are kept by those interested in them, in different parts of the docks, instead of being conveyed to one centre. In one such collection as these we saw several articles which, though commonly imported, are seldom seen except by dealers, in their natural state, simply because the sole object for which they are imported is for the adulteration of other articles. Of such we may mention what are known in trade as mother Cloves, which are the fruits of the Clove tree (*Caryophyllus aromaticus*). They are black, fleshy-looking ovate oblong fruits, about an inch in length. Flückiger and Hanbury, in their excellent *Pharmacographia*, describe them as being much less rich in essential oil than Cloves, and further say that "though occasionally seen in the London drug sales in some quantity, they are not an article of regular import. As they contain very large starch granules, their presence as an adulteration of ground Cloves would be revealed by the microscope," nevertheless we are assured that they are used for the above purpose. That these mother Cloves are sold at a very low price is evident by a note in the work above referred to, to the effect that in a fortnightly price-current of a London drug-broker, dated Nov. 27, 1873, occurs an announcement of the sale of 1050 bags of mother Cloves at 2*d.* to 3*d.*

Another product of the Clove plant, which is imported in larger quantities, is the stalks of the flowers or flower-buds. These appear to have been known from an early period, for we gather again the following information from the *Pharmacographia*, where we are told that Clove stalks "were an article of import into Europe during the middle ages, when they were chiefly known by their low Latin name of *Justi*." Both the stalks and leaves of the Clove tree seem to have been articles of trade at Constantinople about the middle of the 14th century, and the latter were imported into Palestine so early as the 12th century, and likewise occur in a list of drugs sold at Frankfort about the year 1450. They are not known to be in use anywhere at the present time though the stalks are "still a considerable object of trade, especially from Zanzibar, where they are called by the natives *vibunia*. They taste tolerably aromatic, and yield 4 to 5 per cent. of volatile oil; they are used for adulterating the ground Cloves sold by grocers. Such an admixture may be detected by the microscope, especially if the powder after treatment with potash be examined in glycerin. If Clove stalks have been ground, thick-walled or stone cells will be found in the powder; such cells do not occur in Cloves." Thus three distinct products are furnished by the Clove plant, though they all have the same economic application, that of a spice.

Under the name of "Myrobalan flowers," some peculiar hard, brownish irregular objects attracted our attention. That these were no flowers; or even fruits was apparent on cutting one through, which solved the secret of their being galls. These galls, or so-called Myrobalan flowers, which appear to contain a large quantity of tannin, are gathered from the trees of the species of *Terminalia* yielding the Myrobalans of commerce. Whether, however, they are produced equally from *Terminalia* *Chebula*, *T. Bellerica*, and other species we are not able to say. It seems, however, that they are imported for the same uses as true Myrobalans, namely, for tanning.

A peculiar looking fruit, divided into from five to ten carpels, but united into a point at the apex, is imported from San Domingo under the name of "Flor de Cuzep." Each fruit is about the size of a Walnut, hard and brittle, of a dark brown or blackish colour, and contains a large quantity of dark, brittle resin; the whole fruit burns freely, in consequence of this resin, and gives off a balsamic but not odoriferous fragrance. They are the produce of *Clusia rosea*, and are imported only occasionally, it is said, for the sake of the resin. Indigo, it is well known, is the produce of *Indigofera tinctoria* and *I. Anil*, and perhaps other species growing in the East and West Indies, South America, &c., and is obtained by cutting down the plants and throwing them when freshly cut into water, in which they thoroughly macerate for some hours, when the liquid is drawn off and thoroughly stirred and beaten with bamboos or poles; the blue colour settles at the bottom of the vessels in the form of a sediment or mud, which is afterwards boiled for some time, and finally spread out on canvas frames to com-

pletely drain and dry, when it is cut into cubes or made into bales, and is ready for exportation. As many as 88,680 cwt. of indigo from all countries were imported into England during 1876, of the computed value of £2,129,986. The bulk of this, however, is reshipped to the Continent, our average consumption ranging between 15,000 cwt. and 20,000 cwt. At the time of our visit to the docks a very large quantity of Guatemala indigo was then in store. The packages or serons are formed of bullocks' hides, laced up very tightly with strong cord, the hairy part of the hide being inside. After being emptied of the contents these hides are sold to the tanners, fetching on an average about 2*s.* 6*d.* each.

It is needless to say that the area over which the dock premises extend is something enormous, though we are unable to give the extent in acres. It will suffice to show that the distance from the warehouses in which are stored the articles just described to the timber sheds, where is stacked vast piles of foreign timber, is quite a journey. On our way we pass piles upon piles of a dark, nearly black wood, in uniform lengths of 4 or 5 feet. Each piece shows plainly that the sap-wood has been roughly removed, and the whole has a weather-worn appearance. These numerous piles are all Logwood (*Hæmatoxylon campechianum*), a valuable black or deep red dye-wood, brought annually in very large quantities from Campeachy, Honduras, and other parts of Central America.

In the timber sheds—that is, under cover, but open at the sides—are quantities of *Lignum-vite*, the immensely hard wood of *Guaiaecum officinale*, which is imported from Jamaica, and used chiefly for blocks and pulleys, skittle-balls, pestles and mortars, rulers, &c. *Satinwood* is also found here in thousands of billets, but upon inquiry we were told that the bulk of the *Satinwood* now imported is not brought from Ceylon, but from the West Indies, and chiefly from Bahamas. It is, therefore, conclusive that the wood is not that of *Chloroxylon Sweetenia*, which is usually known to botanists as the tree furnishing *Satinwood*, but is probably the produce of some ebenaceous tree—the *Dominica Satinwood*, which is of a bolder figure than that of Ceylon, being derived, it is said, from a species of *Maba*: the logs occur in long square pieces about 6 or 8 inches thick. The East Indian wood is mostly imported in circular logs, and is not now so highly valued as that from the West.

It is impossible to notice even a tithe of the woods found here, but before leaving the sheds, and thus concluding our visit to the docks, we are struck with wonder at the immense size of some logs of mahogany; many of them appeared to be quite 20 feet long, and perhaps 3 feet square. The trunks after being felled are roughly squared to enable them to be more conveniently carried on tracks to the rivers to be floated down to the coast; some of the logs indeed are said to be so large as to be impossible to remove from the place where they were first felled. Looking at the logs as imported it seems wonderful that they could have been brought over the seas in sufficient quantity to make them remunerative.

As we before said, many are the lessons to be learnt from a visit to such places as our import docks. The time thus spent is certainly not wasted. *Y. R. Y.*

ABIES ENGELMANNI.

YOUR correspondents who have been trying to clear up this knotty point appear only to get deeper into the dilemma.

I went over to Knap Hill the other day, partly to see Mr. Waterer's very beautiful *Rhododendrons*, but principally to have a peep at the new Spruce, about which we have heard so much. When I saw it I immediately recognised a very old friend, which, rightly or wrongly, we have been selling for the last ten years under the name of *Abies Engelmanni*.

The plants which Mr. Waterer had under that name were so disfigured by spring frosts that they were very difficult to recognise, and I hesitated to express an opinion, although I had a very strong suspicion of what they were, which suspicion was thoroughly verified yesterday on comparing one of these plants (which Mr. Waterer at my request kindly forwarded to us) with a batch of plants in our possession.

In 1875 we purchased at Messrs. Stevens' auction rooms two parcels of seed under the name of *Abies Engelmanni*; after a time we discovered that we had two distinct varieties, one lot being the *Abies Engel-*

manni, which is correctly described by M. André, with leaves very thickly set on the upper surface of the branchlets, slightly recurved and appressed, and shorter, thinner, and much less sharply pointed than the other variety, which is correctly described by Gordon on p. 5 of the last edition of his *Pinetum*, under the name of "*Abies commutata* Parlature, Engelmänn's Spruce, syn., *Abies Engelmanni*, Parry. Leaves thickly crowded all round the branchlets, three-fourths of an inch long, four sided, rigid, smooth, sharp-pointed, and either straight or slightly curved, particularly when young, and of glaucous white colour."

This description is perfectly correct, with the exception of the colour, which only applies to a portion of this variety, many being of a dull green colour, and others of every shade of glaucous green, some with a far bluer tint than is ever seen on *Picea nobilis*.

The former of these varieties we soon discovered was utterly worthless, each year being cut by spring frost; we therefore ceased to sell it, although it is still growing in our nursery; and I may here say that this plant is identical with that grown by Mr. Waterer under the name of *Abies Engelmanni*. I have also found it growing in Continental nurseries under that name.

The other variety, which is identical with Mr. A. Waterer's *Abies Parryana*, we continued to sell under the name of *Abies Engelmanni*, the glaucous specimens at a high price.

It fully deserves everything that has been said in its favour. It has never been touched by any frost, and will grow and thrive in the bleakest situations, where all other *Abies* (at any rate as single specimens) are cut to pieces. Messrs. Fisher, Holmes & Co., of Handsworth, have a large batch raised from seed purchased at the same sale, and will fully bear me out in what I say. Whether they had any of the worthless variety among theirs I cannot say, but it is very strange that out of a batch of four-year-old seedlings raised again from two parcels of seed purchased at Messrs. Stevens' under the name of *Abies Engelmanni*, one lot has turned out the worthless variety, and the other the good one. The question still remains which of the two is *Abies Engelmanni*? If the first, then ought not the other one to be called *Abies commutata*?—as this is the variety described by Gordon under that name, and evidently the one referred to by M. Roetz in his letter to M. André.

I had a conversation with M. Roetz at Cologne in 1875 about *Abies commutata*, and from his description I came to the conclusion that it was identical with the plant which we were selling as *Abies Engelmanni*.

Since writing the above I have carefully read Dr. Engelmann's description of *Abies Engelmanni*, published in the *Gardeners' Chronicle* of October 31, 1863, and I have come to the conclusion that the early growing worthless variety is the one intended. The plant there referred to as *Picea Menziesii* I fully believe to be the *Abies Menziesii* Parryana of M. André, or *Abies commutata* of M. Roetz.

And now I come to the gist of the matter. I must enter my protest against *Abies Menziesii* being mixed up in the controversy at all. *Abies Menziesii*, true, is a distinct species from either, and is not, that I am aware of, found in that locality, its habitat being in Northern California, and a variety of it very distinct although given by some authorities as a synonym, viz., *Abies sitchensis* being found as far north as the island of Sitka.

The leaves of *Abies Menziesii* are much longer, wider and thinner than those of the variety which I will call for convenience *Abies commutata*, a leaf cut in two and strongly magnified presents a totally different section. The leaves are much more thinly set, and only on the upper side of the branchlets, they are a vivid green above and glaucous beneath, whereas *Abies commutata* is rather more glaucous above than it is beneath.

The habit is totally different, and the growth of *Abies Menziesii* in one season is double that of *Abies commutata*; above all, the cones are dissimilar.

I have before me a cone of *Abies Menziesii* grown at Elvaston Castle, also a cone of *Abies Menziesii* pulled from a tree in the Rocky Mountains in Northern California by our Mr. Syme, likewise a cone of *Abies commutata* sent home by M. Roetz in 1874, which, from his letter, is undoubtedly the same as the plants referred to as growing in Denver city, and in Professor Sargent's garden at Brookline.

The cones of the two species differ considerably, although I do not dispute that they are nearly allied.

We have seedlings raised from seed sent out by M. Orties in 1875 through Messrs. Sander & Co. as *Abies commutata*, which we fully believe to be the right thing, but it is impossible to speak positively about such young plants. The question now is what is to be the name, as most certainly it is deserving of a name to itself, and should not be hung on to *Abies Menziesii*, from which it so much differs. *John Barron, Elvaston Nurseries, Borrowash, Derby.*

NOTE ON THE MIMULUS LUTEUS.

MANY years ago my attention was drawn to the excitio-contractility exhibited by the lipped stigma of *Mimulus luteus*, the structure of which I then gave an account of in the *Proceedings of the Edinburgh Botanical Society*. In connection with my recent investigation of the excitatory variation in *Dionaea* I have, during the last few weeks, in co-operation with Mr. Page, made experiments for the purpose of ascertaining whether in this organ, as in the leaf of *Dionaea*, the change of form provoked by mechanical stimulation is accompanied by a similar electrical disturbance.

Mimulus luteus is a favourite window plant on account of its showy flowers, and the facility with which it can be cultivated. The mechanism of the contraction of the stigma can be best studied in the inferior of the two lobes, of similar size and form, of which the organ consists. In the unexcited state, when the flower is in full bloom, this lobe is curled outwards. The curling outwards is due, as I long ago observed, to the turgidity of the layer of loosely connected conducting cells, ending in papillae, which constitute the stigmatic surface. So long as this tissue is turgid the elastic lamina by which it is backed is prevented from straightening itself, so that the whole lobe forms a scroll of which the axis is transverse. The effect of touching any part of the lobe, and particularly the papillary surface, is to diminish the turgidity of the tissue, as the result of which the organ slowly expands so as to face and ultimately meet its fellow.

The excitatory change of form which I have described is, as in the case of *Dionaea*, associated with an electrical disturbance, of which the following are the most important features:—(1.) The sign of the variation is the same as in *Dionaea*, the excited structure becomes negative to the rest of the plant. (2.) The extent of variation is somewhat less than in *Dionaea*, the electromotive force developed between the stigma and style being usually about twenty-five thousandths of a Daniell, whereas in *Dionaea* the variation may amount to from forty to fifty thousandths. (3.) The variation is of relatively long duration; it reaches its maximum at the ordinary temperature of summer, about five seconds after excitation. It subsides at first rapidly, then very gradually, so that the effect may not have entirely passed off until two or three minutes have elapsed.

As in *Dionaea*, the period of electrical disturbance is shortened by increase of temperature. Thus in five stigmas in which the period was measured at 20° C. (68° Fahr.), and at 37° C. (95° Fahr.), the mean duration of the interval of time between the commencement of the electrical disturbance and the moment at which it began to subside was 6.2 sec. at the higher temperature, and 3 sec. at the lower.

In general, the stigma, when in the unexcited state, is positive to the style. As, however, it can be shown that other factors, not concerned in the excitatory process, are operative in the production of this result, not much importance is to be attached to it.

I send this short note in order that physiologists interested in the subject may be able to repeat the observations during the present season. *J. Burdon-Sanderson, University College, June 27, in "Nature."*

THE ROYAL GARDENS, KEW.

[We take the following extract from the Report of the Director for the year 1876, just published. EDS.]

BOTANIC GARDENS.—The further rearrangement of the plants in the Palm-house was proceeded with in the course of last spring, and may now be regarded as practically completed. A great improvement has been obtained in the general effect. As mentioned in my report of last year, it has been found necessary to cut down nearly all the large Palms on the north side of the transept, and plant out others in their place. The following are the more important changes:—

Arenga saccharifera, cut down and replaced by

Sabal glaucescens; *Livistona inermis* (L. australis), *Bot. Mag.* 6274, cut down and replaced by *Phoenix dactylifera*; *Sabal glaucescens*, transplanted and replaced by *Astrocaryum rostratum*; *Acrocomia sclerocarpa*, cut down and replaced by *Thrinax aculeata*; *Sabal umbraculifera*, cut down and replaced by *Livistona chinensis*; *Veitchia canterburyana*, transplanted and replaced by *Ceroxylon andicola*; *Phytelephas macrocarpa*, removed and replaced by *Attalea Cohune*. *Areca alba* cut down and replaced by *Euterpe pisifera*.

A selection of the larger tropical Ferns, Aroids, Marantaceae, &c., have been planted in the beds under the Palms, which have hitherto been quite bare. They now are covered with an undergrowth of singular picturesqueness and luxuriance. The gigantic Screw Pines (*Pandanus*) which are such a conspicuous feature in the north wing are rapidly becoming too large for the positions they occupy; and as it is impossible to give them more space, they will have to be cut down in the course of one or two years at the farthest.

I must again urge the desirability of a reform in the heating apparatus of this house, as detailed in my last year's report, as a measure of economy even more than of efficiency. With the exception of the immense improvement in both heating power and reduced consumption of fuel, obtained by bringing the flues up through the roof of the wings instead of conducting them underground to the shaft near the Richmond Road, no material improvement has been introduced into this building since its construction nearly thirty years ago. The re-arrangement of the staircases leading to the gallery, proposed in my last report, has been reported upon by the Board's works' department, and unfortunately proves to be impracticable. Some means of draining off the moisture due to condensation which accumulates on the gallery floors during the winter is however urgently needed.

In the AROID HOUSE (No. 1) the superb tropical Tree-Fern (*Cyathea princeps*) having outgrown suitable dimensions, was with great reluctance on my part taken down in the course of the summer, and replaced by a smaller specimen from the tropical Fern-house.

The whole collection of Aroids has been very carefully revised, and a catalogue prepared by Mr. Brown, second assistant in the Herbarium. It comprises upwards of 300 species, and should eventually be printed for distribution to other botanical establishments. The whole collection of Calami (*Rattan canes*) is now also arranged in this house, the most heat of which suits them better than the Palm-house.

The FERN-HOUSES (Nos. 2 and 3) retain their pre-eminence, whether for the number of species in cultivation or the health and vigour of the plants; but the constant humid temperature necessary to their growth so damages the painted woodwork of the houses that they are under frequent repair. I am strongly of opinion that, seeing how much shade Fern-houses require, the side walls should be of brick up to the eaves, with large side sashes, and that the woodwork of both roof and sashes should be of some of the durable colonial woods, as the Jarrah of West Australia, which would probably not require internal painting.

The species of *Cheilanthes* in the Cool Fern-house which have proved very impatient of pot culture have been planted on a broad side shelf covered with stones, pots, and soil well drained below, and promise to do well under this treatment. Many of the smaller Ferns in the same house, which, when in small pots, were watered either too much or too little, have been similarly accommodated with obvious success.

The number of species and varieties of Ferns in the Royal Gardens is now upwards of 1000.

The labour and expense of keeping up both the interest and beauty of the ORNAMENTAL CONSERVATORY (No. 4) throughout the year, by a mixture of commoner with the rarer ornamental plants, is a subject to which I have, especially of late, devoted a considerable amount of attention. It has occurred to me that as regards the common plants of merely decorative interest, of which it is desired to display a fair quantity as affording a very great gratification to many visitors, it might be more economical and satisfactory to buy than to raise them ourselves, and to devote our attention to the cultivation of the rarer sorts alone and to purchase the commoner.

The SUCCULENT HOUSE (No. 5), which is by far the most interesting in the garden in respect of the magnificent collection of plants of grotesque habit and

singular form, has also been re-arranged, and some of the large duplicate *Euphorbias*, *Aloes*, and *Cacti* removed to the Palm-house. Several of the largest *Agaves* and *Fourcroyas* (commonly called American *Aloes*) have flowered during the past summer, and the flowering stems rising to a considerable height were allowed to pass through the roof, presenting a striking and singular appearance.

The collection of ECONOMIC PLANTS has been carefully revised, extended, and entirely re-arranged. It is now probably one of the most complete series of medicinal and useful plants ever brought together. The nomenclature has been checked and a manuscript catalogue prepared.

The following plants of especial botanical interest, amongst others of less importance, have flowered during the past year in the Royal Gardens:—

- | | |
|--|--|
| Agave dealbata, Lem. | Bot. Mag. 6236 (from rhizomes sent to Kew from the Falklands by Mr. Mosely, Naturalist of H.M.S. "Challenger") |
| ,, ensiformis, Hort. | |
| ,, micrantha, Salm-Dyck. | |
| ,, Sartorii, K. Koch; Bot. Mag. 6295 | |
| Albucca junceifolia, Bak., n. sp. | Stapelia Sarpedon, N. Br., n. sp. |
| Anthericum Gerrardi, Bak., n. sp. | ,, varians var. adnata, N. Br. |
| Bongardia Rauwolfii, C.A.M., Bot. Mag. 6244 | Telfairia occidentalis, Hook f.; Bot. Mag. 6272 |
| Chlorophytum arundinaceum, Bak., n. sp. | Thamnocladium Falconeri, Hook. f. (erroneously known in gardens as <i>Arundinaria falcata</i> , Nees) |
| Dasylirion glaucophyllum, Hook.; Bot. Mag. 5941 | Tulipa Hageri, Heldr.; Bot. Mag. 6243 |
| Fourcroya gigantea, Vent. | Tapistra macrostigma, Bak.; Bot. Mag. 6230 |
| Fritillaria recurva, Benth.; Bot. Mag. 6264 | Turraea obtusifolia, Hochst.; Bot. Mag. 6267 |
| Gasteria dicta, N. Br., n. sp. | ,, fiformis, Haw. |
| Mesembryanthemum vittatum, N. Br., n. sp. | Moricandia sonchifolia, Hook. f.; Bot. Mag. 6243 |
| ,, fiformis, Haw. | Oxalis encephalylla, Cav.; |
| Moricandia sonchifolia, Hook. f.; Bot. Mag. 6243 | |
| Oxalis encephalylla, Cav.; | |

I may take this opportunity of noting that a well-known stove foliage plant of gardens, *Theophrasta imperialis*, Linden, proves from the examination of specimens in fruit sent to us by M. Glaziov, to be a species of *Chrysophyllum* belonging to a different natural family, Sapotaceae.

ARBORETUM (IN THE PLEASURE GROUNDS).—The digging of young plantations, trenching for new ones, and removal of dead and dying trees, continues to absorb much of the labour of this department.

Flagstaff Dell.—The old gravel pit having been laid out as described in my last report, has been planted with the classified collection of shrubby *Poly-petalae* (*Thalamiflorae*). They comprise 56 genera and 500 species and varieties.

INTERCHANGE OF PLANTS AND SEEDS.—The receipts during the past year have been 6033 plants of all kinds and 2487 packets of seeds, from 244 contributors.

BALSAM OF COPAIBA.—Some well-ripened seeds of the Para *Copaiba* ("*Copaifera multijuga*") have been brought by Mr. Cross from the forests of Para, and germinated freely. The tree which produces it is described as gigantic, the trunk sometimes rising to a height of 80 feet before branching. The Para balsam, called *Copaiba blanca*, is chiefly sent to France, where it obtains the highest price of any. A single tree, if tapped at the right season, is said to yield about 84 imperial pints of balsam. Very little is known of the history or botanical characters of this plant, which has been only imperfectly described. It is greatly to be desired that this tree should be introduced into the East Indies.

BALSAM OF PERU.—This beautiful tree (*Myroxylon Pereirei*) was introduced into Ceylon in 1861 by the exertions of the late eminent pharmacist, Daniel Hanbury. It has succeeded there admirably, and last year I received several parcels of seeds from Dr. Thwaites, which I have distributed to various tropical colonies. Dr. Thwaites speaks in warm terms of the beauty of its foliage and habit.

CHOCOLATE.—This was introduced into Ceylon, and samples were sent home in 1873. It is now being rapidly improved, and will unquestionably soon become an important article of trade with that island. I have no further report of its prospects in the Terai district of the Sikkim Himalaya, which is, I fear, too dry for it in winter.

CINCHONA CULTIVATION IN ST. HELENA.—In my report for 1874 I pointed out that "the suitability of the soil and climate of that island for *Cinchona* cultivation has now been indisputably proved." It is a melancholy conclusion to the efforts made by Kew on behalf of this doubtless dispirited, but I am afraid I must add spiritless, colony that nothing has been done to utilise so easy a source of revenue. In a private letter recently received, I am

informed, "up to within a few months since a man was paid by the colony to look after the Cinchona plants on Diana's Peak, but even he has been disestablished, and the plants are overgrown and almost hidden in Ferns and dense undergrowth of native vegetation."

(To be continued.)

Foreign Correspondence.

SPRING IN MINORCA: *Balearic Islands, Spain.*—There is a small mail steamer, of about 350 tons burdeu, which leaves Barcelona every Tuesday, at 4 P.M., for the island of Minorca. This steamer reaches Aleudia, a port on the north-east coast of Majorca, the next morning at 5 or 6, then crosses the strait which separates the two islands, and reaches Port Mahon, at the southern extremity of Minorca, about 2 or 3 in the afternoon. The entire voyage from Barcelona thus occupies about twenty-two hours. Wishing to join this steamer at Aleudia on the Wednesday morning, I had to sleep there. The road from Palma crosses the level plain which occupies the centre of the island, deflecting to the north-east. There is a railroad, recently opened—a satisfactory evidence of incipient energy and progress, entirely constructed by Majorcan capital, which is destined to connect the two towns. It is, however, so far only completed to Inca, a small agricultural town of the central region. Eight or ten miles of road have still to be got over in the omnibus, a species of covered cart on half-springs, holding eight persons, including the driver, very much like an old-fashioned English market cart.

MAJORCA.

The country that we traversed was thickly studded with villages and small towns, and carefully cultivated. The rocks that occasionally showed themselves through the soil were limestone, and the agricultural produce was principally, indeed all but entirely cereals—Wheat and Barley; the grain fields being dotted, at the distance of thirty or forty feet, by Almond, Fig, Carouba, or Olive trees. It appears that these fruit trees greatly add to the value of the land, and, consequently, to the rent paid for it.

We found homely but clean shelter at the little *fonda* at Aleudia, an old Moorish fortified town, with ramparts and ditch still intact. We were roused at 5 the next morning to proceed in our market-cart omnibus to the port, about a mile distant. There we saw the Barcelona steamer lying at ease on the green Mediterranean waters, and by 6.30 were fairly off. The Bay of Aleudia is wide, deep, sinuous, and affords perfect shelter in deep water from all wind but the north-east, to which it is quite exposed, as is Majorca generally. Aleudia is only 24 miles distant from Cindadela, the capital of Minorca, but directly opposite, at the northern extremity of the island; whereas Port Mahon, which occupies the south-eastern extremity, is 45 miles distant. The weather was fine, but there was a heavy swell running, the remains of a former gale, so our little steamer rolled very freely. The French steamers for Algiers pass through these straits on both journeys, and we were fortunate enough to cross the bows of one of the largest as it calmly advanced on the rolling waves like a floating castle. We were dancing about on the top of the swell in our small craft, and envied the majestic steadiness of the *Said*. This fine ship was crowded with passengers, who lined the side next to us, watching, no doubt, our erratic movements with deep commiseration.

PORT MAHON.

After a passage of six hours at half-past 2 we entered the splendid harbour of Port Mahon. It is 3 miles in depth, and protected from every wind by its sinuous, serpentine character. Port Mahon is said, indeed, to be one of the finest harbours in the world. The town is situated on its inner and western shore on a rocky elevation, about 70 or 100 feet above the sea level. We found very comfortable accommodation at a small *fonda*, or inn, with sash windows, as in England, and the cleanliness of which was beyond all praise. The entire town is clean beyond belief or description, the houses appearing to have been recently whitewashed both inside and out, and the streets being cleansed and brushed that a pin would be seen on the ground. This extreme cleanliness continued to be the characteristic of the island wherever we went. Villages,

towns, lone houses, all must be whitewashed, inside and out, every month, week, or day, for the walls are all white as snow. Indeed, I was told that whitewashing is a national tendency or craze, and that if a Minorcan gains a peseta (10*s.*) he spends a quarter of it in whitewash! I felt quite humiliated at my own individual shortcomings, and determined that when I reached home again I would imitate my Minorcan friends, and begin a vigorous and oft-renewed white-wash crusade on my own premises.

It is, no doubt, owing partly to this whitewashing mania, and to the horror of dirt which it implies, that Minorca owes its reputed great healthiness and its special freedom from zymotic or dirt diseases. The custom gives a very peculiar character to the landscape, for as the roofs are often whitewashed as well as the walls, the houses, villages, and towns stand out in the glare of the sunshine like masses of chalk. Is this excessive cleanliness owing to Minorca having been during the greater part of the eighteenth century in the possession of the English, or is it a remains, a trace of early possession by the Moors, who reigned over it for centuries?

Minorca is 33 miles in length and 13 in breadth where broadest, the circumference is 62 miles, and the area 300 square miles. Its longest diameter is N.W. by S.E., the latitude is 39° 47', longitude between 3° 50' and 4° 23' E. It presents the character of a rocky, undulating plain, with a ridge of hills running across the island in a slanting direction, from north-west to south-east. This ridge culminates in the centre of the island near the eastern coast, at Monte Toro, about 700 feet above the sea. The southern third of the island has not even this slight barrier to the north winds. It is totally unprotected.

VEGETATION OF THE ISLAND.

Wishing to study the vegetation of the island we took a carriage to Cindadela, the capital, 24 miles north of Port Mahon, making a leisurely progress one day, and returning the next. This journey proved a very pleasant and a very interesting one. The road, which passed through the centre of the island, was very good, and the covered omnibus market-cart which conveyed me and my companion was of a much better description than those we had ridden in at Majorca. It was on firm wheels, and was supplied with much better springs. These conveyances are, no doubt, the very thing for the climate of the Balearic Islands, which, during a great part of the year, is characterised by ardent sunshine, intense glare, and much dust.

The groundwork or skeleton of Minorca is a secondary limestone, but the ridge of hills that crosses the island is volcanic, and probably connected with some similar development in Majorca, for the direction of the mountain chains in the two islands is all but identical.

The weather was lovely, enchanting, as I have always found it in the Mediterranean in the month of May—the mid-day heat in the shade being 74° or 75°, and the night temperature from 60° to 68°. Every plant was green, fresh, beautiful; the sky clear, with only a few fleecy clouds, and all Nature was bathed in glorious sunshine.

In the lower or southern third of the island there are scarcely any trees, owing to there being no protection whatever from the sea winds from whence-soever they come. The country, rocky and undulating, is cultivated all but entirely with cereals. Barley quite ripe, partly cut, May 10; Wheat turning colour, and here and there a field of Oats. What is not under cereals, or fallow, was planted with broad Beans, ripening; Potatoes, 18 inches high, in flower; and red Clover, recently introduced, and thriving on the most sterile limestone soils. Formerly the Vine was extensively cultivated, and much wine made; but the oidium destroyed the Vines, and they have been replaced by cereals. The ground was divided into small fields separated by walls 3 or 4 feet high, and 2, 3 or 4 feet wide, made with the stones taken out of the fields. Here and there were rocky patches in the process of formation into fields by the clearance of the stones and rocks, and by their erection into walls. Where the road was below the surrounding level, in slight depressions of surface, not yet brought into cultivation, I recognised the old familiar plants of the Mediterranean limestone flora, the "maquis" of Corsica and of Sardinia, *Lentiscus*, *Alaternus*, *Cistus*, *Smilax aspera*, Prickly Broom, Blackberry, Honey-suckle, *Asphodel* out of flower; *Ferula*, the same; *Convolvulus*, variegated Thistle, *Geranium*, *Cine-*

raria maritima, the universal Shepherd's Purse, *Gladiolus*, *Chrysanthemum segetum*, Myrtle, Rosemary, Thyme, Rue, &c. Evidently this part of Minorca was, once upon a time, covered with this kind of vegetation, and if left to itself for a few years would soon return to the wild state, and be covered by these plants, the denizens of the warmer regions of the Mediterranean, or limestone soils.

About 9 miles from Port Mahon we reached the base of the interesting ridge of hills, at the foot of which, slightly protected from the north-east winds, vegetation became more luxuriant, Fig trees and small Olive trees appearing. Up to that time all watercourses had been quite dry; they were clearly mere winter torrents, full for an hour or a day, and then dry. Here we saw a small watercourse, a mere rivulet, all but dry, fringed with Tamarisks. I looked for the Oleander, the usual companion of the Tamarisk along the beds of streams and torrents in Algeria (only 190 miles distant), but I did not see any. The Ilex, or evergreen Oak, a common Mediterranean tree in schistic, granitic soils, also appeared.

The road entered a depression in the hills, and the nature of the soil and rock changed, becoming schistic, volcanic. The Ilex were more numerous and larger, and the brushwood was principally composed of *Arbutus*, Mediterranean Heath, *Calluna vulgaris*, and *Cistus* or Rock Rose, as is usually the case with such soils in the Mediterranean. After winding for a few miles through these low hills, covered with a thicket of Ilex and brushwood, we again emerged into a calcareous rocky plain, which reproduced the vegetation and cultivation of the southern region already described, reaching Cindadela for dinner.

CINDADELA.

Cindadela is a very clean "whitewashed" little town, with a population of 8000. It is the legal and Government capital of the island, Port Mahon being the commercial and military one, with a population of 18,000. The fortifications still extant are of Moorish origin. Here we got very comfortable and exquisitely clean accommodation, at an inn kept by a man who had been many years cook on board a United States man-of-war, and who received me and my companion most cordially. There was a public garden at Cindadela, a *rambla*, as it is called in the north of Spain, and I made a note of what I found, viz., white Lily, red Valerian, *Nasturtium*, Wallflower, Hollyhock, *Centifolia* Rose, Bengal Rose, *Cytisus*, Poppy, *Antirrhinum*, *Adonis*, fancy *Pelargoniums*, very poor; Oak-leaved *Geranium*, Sweet Pea, *Phlox*, *Carnation*, *Delphinium*, and two or three Palms, 30 feet high, the only ones I saw in Minorca. All these were in full flower, and were thought by the natives to constitute a marvellously beautiful and choice garden. They are found in all gardens of the Mediterranean islands and shores, constituting the principal spring garden flora. I presume they occupy the same position of honour in "cottage gardens" all over the temperate regions of the world.

WHERE THE ORANGES GROW.

Both at Port Mahon and at Cindadela there were plenty of Oranges to be had, and yet after crossing all but the entire island I had not seen a single Orange tree or shrub. Where could they come from was the question I asked. I was told that they all came from one garden or orchard, an hour's ride from the village of Ferarias, a few miles from Cindadela, near the main road; so we determined to stop on our way back and examine this wonderful orchard, the existence of which on an exposed island like Minorca puzzled me greatly. Two hours' drive brought us the next day to Ferarias, where we mounted donkeys, and scrambled over rocky hilly paths for an hour in the glare of the sun, without seeing the vestige of a garden, of trees, or of anything else but the field and occasional hedge or wall vegetation already described. We were nearing the sea also, and between us and it there seemed to be nothing but stony eminences, declivities, and stone-enclosed fields planted with cereals. All at once our guide pointed to a cleft in the rocks on our left, the beginning of a sinuous depression which, at 100 yards' distance, seemed like the depressed bed of a river, occupying a gorge with cliffs on both sides. Our donkeys entered the cleft between two rocks, 20 feet apart, by a narrow path, and we at once found ourselves in cool welcome shade, in the midst of most luxuriant vegetation. The path and the valley or gorge soon expanded, and we discovered

that we were truly in a "happy valley." We had been transported in two minutes from burnt-up, scorched rocks, with a scanty spring vegetation, to a tropical forest of Pomegranate trees, quite timber trees, Orange, Lemon, Fig, and Olive trees, growing in the greatest possible luxuriance. The ground and rocks were covered with rank grasses, with Buttercups, Periwinkle, Geranium, Sage, Docks, Ivy, Clematis, and with *Capillus-Veneris*, *Scolopendrium*, and *Polypodium vulgare* Ferns.

This wonderful valley is a mere cleft, rent, depression in the calcareous rocks of this part of the island. It is about 1½ mile long, sinuous, of variable width, from 50 to 300 feet, with cliffs about 150 feet high on the west side, and about 70 feet or 100 feet on the east. It reminded me very much of the sinuous cleft, depression, gorge, or valley which constitutes the

If few they are large, if numerous small, as is the case with fruit in general. The contrary opinion reigns all over the western Mediterranean. The large Majorca Oranges, which are always sold at 20c. a piece, twopence, are supposed to be a distinct species. As usual with all fruit, not only is the size thus increased, but the flavour seems to improve along with the size.

Thus in Minorca the *Ferarias* Orange orchard reproduces in a different way the history of the Soller Valley Orange orchard in Majorca. The one is a gorge, or fault in the rocks, thoroughly protected from winds, as the other is a kind of crater-like amphitheatre, also inaccessible to wind. Both are natural stoves, orchard-houses, offering complete protection from every wind, which seems an indispensable condition to Orange culture.

shores and islands that I have studied and described in my large work, *Winter and Spring on the Shores and Islands of the Mediterranean*. F. Henry Bennet, M. D., *The Ferns*, Weybridge, June 15.

PHENIX RUPICOLA.

This very graceful Palm is described by Mr. Bull, to whom we are indebted for the accompanying illustration (fig. 4), as being of acanlescent habit while young, with wide-spreading arching pinnate leaves, having a slender rachis and very short petiole, which is dilated at the base and partially encircles the growing point. They are broadly lance-shape in outline, with long narrow pinnæ, the lower of which become gradually reduced to spines. It is an introduction from India, and promises to prove of great value as a decorative plant.

Natural History.

BIRD'S NESTS.—In the *Gardeners' Chronicle* of the 30th ult. I see that a correspondent draws attention to the fact of a pair of tomtits having built their nest in a pump. For three years past a nest has been built by tomtits in a disused pump in the stableyard here. This year four out of a hatching of seven young birds left the nest just three weeks ago. The entrance to the nest was by a hole under the handle. This hole, however, was not the sole channel of egress, for I have several times witnessed the old birds coming out by the spout.

Nearly or about the same time that the young tomtits left the nest I found some young blackbirds seated on the branches of a Laurel, in which there was a nest. They had evidently only just a few moments before got out of the nest, for the old birds were calling to them. I caught a couple of the young birds, and took them indoors to show my children, the hen bird following me into the inner hall right up to the drawing-room door. After showing the young birds to the children, I replaced them on the Laurel, and had the satisfaction of seeing them go off with the parent birds. Two days afterwards, bearing the call of a blackbird, such as is made by the old to the young birds, I walked out of my study, and there in the inner hall was a hen blackbird close up to the drawing-room door. Whether it was the same bird or not of course I cannot tell, but the circumstance seems very much as if it were an exhibition of the instinct existing in birds which led the old bird—say, on missing its young again—to return to the place whence they were returned to the tree on the previous occasion of their loss.

If the above notices of birds are out of the scope of your magazine [by no means], you will, of course, lay this aside; if not, they may interest some who combine a love of wild birds with a love of flowers. F. A. C.

A SUSPENDED SWALLOW'S NEST.—It may very probably interest some of the readers of the *Gardeners' Chronicle* to read the following, which occurred some time since. My late father had a round Tulip bed, and for the protection of the buds and blooms from the sun, &c., he had a wicker covering made of Willow rods, similar to a lid of a basket, and resembling an umbrella, with a hole in the centre for a stick to be placed from the centre of the bed, and the cover then put on. After it was not wanted for use the cover was hung up to a beam in a cart-shed by a piece of rope passed through this hole with a knot underneath, and on this knot the swallows built their nest, and as the wind blew it swung about like an umbrella suspended from the top, where it remained for years, as it was then not in use. I am sorry to say the swallows and martens are not so numerous as formerly: as I have a great fondness for them, they receive every protection from injury possible. F. S. C.

Florists' Flowers.

NOTES ON TULIPS AT THE ROYAL NATIONAL SHOW.—FOR now two seasons in succession the Royal National Tulip Show has had to be postponed, and this has certainly been a worse year for the flower than the last. A late bloom is never a long one, nor a good one, when due to severity of weather at a critical time in the growth of the plant. This year April was not kind for Tulips, and May was a joyless and abominable month. The weathercock seemed nailed to the north-east, and the plants could hardly move at a time when their growth should have been rapid, and could not do in a week what should have been a day's work.

FIG. 4.—PHENIX RUPICOLA.

harbour of Port Mahon. But the *Ferarias* valley has no communication with the sea, is much narrower, and its cliffs are higher and more precipitous, its serpentine direction helps to protect it from wind, whenceoever it blows, as is likewise the case with the harbour of Port Mahon.

The central, widest, and most sheltered part of the valley is entirely occupied by large healthy Orange trees, with trunks 2, 3, and 4 feet in circumference, grown as timber trees, and they have not suffered as yet from the *secco*, although I could not discover that they had been grafted. The farmer told us that this orchard not only supplied all Minorca with Oranges, but enabled the owners to export large quantities every year. They had just sent off 50,000, and yet the entire area occupied by the Orange trees did not amount to more than a few acres.

I learnt here, as in Majorca, that the size of the fruit depends, not on the species of the tree, but on the number of fruit the tree is allowed to bear.

IMPORTANCE OF PROTECTION.

The luxuriant vegetation of these sheltered localities reproduces what I have found all over the Mediterranean. Exposure to north winds is quite incompatible with subtropical vegetation anywhere in the Mediterranean, even on its southern shore. The north winds sweep right down into the desert, whenever they meet with no barrier on their way, and peel the rocks, leaving nothing but Pines and aromatic shrubs. Such, however, is not the case with south winds, if there is protection from the north, as evidenced by the Genoese Riviera from Nice to Genoa. In the more sheltered regions Lemon trees clothe the hills down to the sea-shore, and even Orange trees can grow and flourish near the shore if they are protected by a high wall. Thus once more Majorca and Minorca illustrate the lesson of the inestimable value of protection from north winds in estimating climate, and of the extreme influence that it exercises on vegetation in subtropical as well as in northern regions. We see repeated in these islands the facts brought to light in every other region of the Mediterranean

All this stagnation in a plant rapidly and punctually deciduous was sure to have its ill effects, and they were many. Earliest and worst came what is known as "mildew." This attacks the flower-stem at the axil of a leaf, generally either the guard leaf (*i.e.*, the lowest) or the one above it, or else it will appear upon the surface of the leaves themselves. The well-known grey discoloration which it produces spreads very rapidly, rotting an affected leaf, causing an affected stem to fall over, as a ship's mast goes by the board, and injures both the size and health of the new bulb. It is perhaps an after-effect of some mischief first done to the rising plants in April or early May. The foliage seems very hardy, judging by what it will pass through without immediate hurt. But the effects of the shock upon the system are only latent for a while, like the action of a poison; and all at once, upon the very eve of bloom, leaf and stem give way beneath the flower, and it is well if even the bulb survive.

Mildew has been very rife this year, even cutting some beds completely down. Removing affected parts is one way of treating the disease, and perhaps dusting with flowers of sulphur might be useful as checking fungoid growth; but best of all is a watchful attempt at prevention, by taking care that the foliage from the time of its appearance suffers no check or damage, by frost after wet, or by sun upon frost, or by exposure to cutting winds.

The buds themselves suffered much in various ways from continuity of adverse weather. Many on opening showed a rotten petal, and in many the inner petals were oddly crumpled as though they had grown faster than the three outer which enclose them, and which were weatherbound in the bitter wind. There have been also plenty of green and stunted petal tips, and that, too, in plants of which all possible care was taken. Few of us can remember a time that has been so persistently bad for Tulips, though we naturally expect a little rough weather in the best of seasons, and the difficulties make good culture creditable. With me the bloom has been strong and correct, but late and short, and I never knew the plants die down so quickly afterwards. The fact is that the bloom here has been thrown back close upon the usual taking-up time (June 21), and the plants have been punctual in dying down. There has been no interval—no twilight of cool, fading green after the bright day of the bloom. Indeed I am taking them up while yet a few coloured petals cling to pale stalks, like those last stars of tinted lights that will linger on some large pyrotechnic device, when all the rest of the fiery bloom is fallen.

At the Royal National Show no one exhibitor was in the fulness of his strength, either in quality, finish, or size; and therefore flowers won high places, both in the pans and classes, which in a strong year would have had to take back seats.

Along with Mr. Thurston and Mr. Simonite I was one of the judges for the best feathered and best flamed flowers in the whole exhibition; we had, therefore, a critical survey, but we could not find one perfect feathered flower in the whole show—which speaks for the weakness of the year.

There were, however, many fine sorts shown in fine order. Industry, in the "cap stand" was very well done. It is a richly pencilled feathered rose. Mrs. Lee, another finely feathered rose, is still finer when flamed, as it was in the leading stand. Feathered, it will bear no sun, but the colours are faster when flamed. Bessie is a lovely feathered byblöemen—it is of no use if weakly, for the colour is then a feeble brown, and as a flamed flower it is seldom anything. A strong feathered bloom opens greenish white, and then brown, that settles down to almost black and white.

John Morris is a new feathered bizarre with rich long flashed feather, finely pencilled upon a deep golden ground colour, which is alike on both sides the petal—a very important point in the bizarre classes.

Dr. Hardy's famous flamed byblöemen Talisman is a grand flower, always wanted in the best place. There were once a number of feathered breaks of it, but they have largely gone back to a flamed flower. As a feather it is very lovely, and a great addition to a very thin and difficult class; but the only perfectly feathered Talisman I have seen this year was in a cottage garden here. I had given away a few bulbs, and a single Talisman had here done what all my stock,

very much more cared for, have not attempted for several years.

Some Tulips evidently are best when flamed, others as feathered flowers, but Talisman is a gem in both. Old Heroine Tea Rose was again brought forward. She is the feathered form of Triumph Royal, and her "hawk petal" tips seemed to be aggravated by the pinching cold of the season. In the second stand of the leading class there was a new flamed rose—Mary Barber. It was bright, but the gem of flamed roses is Annie McGregor, that broke from a bright red breeder known as Martin's No. 2. The scarlet pencilling of her feather, and the brilliant beam of flame upon the snowiest ground colour, make her a most lovely flower, and she is one of great substance. There was also Clara, a feathered byblöemen of good shape and rich chocolate feather, but in the heavy style, rather plated than pencilled.

In red bizarres, a class that has latterly formed itself by the advent of some magnificent flowers, there were Dr. Hardy and Orion in fine form. These are two flamed flowers, and seem as if they could not feather, the beam is so strongly marked. There was a fine specimen of the late Dr. Hardy's flamed, viz., Ajax—a very distinct flower, and I think a fine thing too, with some growers an admiration of it seems as though it would have to be an acquired taste. It has this year bloomed in splendid flamed character with Mr. Barlow and myself, from a strain marked feathered, which condition is evidently not its forte, though it makes a bold attempt. It is noteworthy that when a Tulip does leave the feathered state for the flamed, it generally makes a beautiful clean flame, as in Heroine to Royal, and Mrs. Lee feathered to flamed. The beam is bright and clean and the flower not "fast" at the bottom, *i.e.*, too heavy with colour. A new rose, breaking from a pink breeder of the very perfection of shape, is Lady Grosvenor, which seems both a feathered and a flamed flower. Modesty is a beautiful feathered Rose, which in the self or breeder state would hardly be kept, being a nondescript colour; only a very correct feather, however, of this sort is worth looking at, for with every defect of colouring there is a dirty stripe or splash of yellow, that it seems to inherit from the breeder form, and which only breaks away in a very clear decided feathered strain. Bacchus, flamed byblöemen, was shown very fine; it is a beautiful constant flower, coming out with the earliest, and though rather thin-looking, living till the last. Mrs. Lomax, which is the same as Mabel, and perhaps even as charming, is beautiful when feathered, and a good marked rose when flamed; the petals turn in at the top, which is more a fault than a beauty. Lady Sefton is a lovely rose, only seen flamed so far; it lives well, and there is a rich vein of pink in the centre of the scarlet beam, which is very beautiful. Ajax has a rich vein of claret in his black beam; and Talisman, a beautiful tint of blue up the centre of his dark purple beam. There is also a grand break of Sir J. Paxton, flamed bizarre, distributed from Mr. Barlow's collection, which is enriched by a dark red beam in the middle of the dark flame. These are all rich breaks, and the rich extra tint is very different from the remains of breeder colour that sometimes haunt a weak break. I saw a bloom of old Lady Crewe, a perfectly feathered old-fashioned rose, but not pure on the stamens, and therefore of a day bygone. Feathered bizarres were not strong this year, though there were some fine attempts by the black and golden Masterpiece, Sir J. Paxton, and Lord Byron, and some seedlings from various exhibitors, and by Mr. Barlow from the late Dr. Hardy's and Luke Ashmole's seedlings, furnished specimens herein. Feathered byblöemen were hard to obtain correct this year, and in the class for them were weak. The strongest flowers as a class were the flamed bizarres, in which, taking both red and dark flowers, we have now some magnificent Tulips. Duchess of Sutherland came often among flamed byblöemen, and is a beautifully pure flower with superb marking; like Masterpiece and a few more, she is better when trained in shape, as the three outer petals are liable to stand away in a triangular manner, known as the "three-cocked-hat" style. Old Aglaia and Triumph Royal are still much wanted for flamed roses, in which we indeed have good flowers, but the best new ones are yet scarce as to stock in hand.

A great deal of interest properly attaches now to the self-coloured classes, technically termed breeders, from which feathered and flamed strains "break." No one can account for this most curious fact in the

physiology of the florist Tulip; we only know of it. Many flowers that were high as feathered or flamed are also very valuable in the breeder form. Witness Sir J. Paxton in bizarres, Talisman in byblöemen, Lady Grosvenor in roses. Indeed, some few are better as self or breeders than as rectified flowers; for some, and they generally the brightest, break into weak coloured strains. Lord Derby is a rose breeder good as anything else. Horatio generally breaks badly, and there are other illustrations of this which might be named.

A new seedling nearly always makes its *début* into the Tulip world as a breeder, and is so shown until there is a fine break—if there is, that is, such a power inherent in it; if not, it must win as a breeder, and say nothing about its failure at higher work.

Glory of Stakehill is a powerful example of a magnificent new seedling, and its mark is made so far as it has been shown. Lady May would have won the position of best breeder in the show if we could have had her a few hours older. She is from the Stakehill collection of breeders, which are the champion team of the day in the seedling department. But it is very encouraging to see the strong array of seedling Tulips that now come to the Royal National shows. They are deserving of a minute separate notice, and they tell of many years of careful work by a fair number of our Tulip growers. *F. D. Horner, Kirkby Malzeard, Ripon.*

Garden Operations.

PLANT HOUSES.

PLANT STOVE.—Allamandas in pots that have now been blooming some time will be benefited by a couple of inches of rotten manure laid on the surface. If this is put on in sufficient quantity to even fill up the pots completely level with the rims, it will, from its loose, open nature, interfere little or none with watering; in a very short time it will be completely filled with a dense mass of roots that will enable the plants to go on making growth and bloom all through the autumn to an extent which they are not capable of by the mere use of manure-water alone, for though the latter is very effectual, still the increase of feeding fibres encouraged by the rich surface-dressing exerts a still greater influence. Bougainvilleas will be similarly benefited by a like treatment. The shrubby-habited Clerodendrons will also produce a much finer second crop of flowers when served in this manner. Plants of *C. Balfourianum* already occupying pots sufficiently large, and that have done flowering and are about to be placed in heat to make growth, will also be much invigorated by surface-dressing of this kind, as also climbing *Thunbergias*, *Hexacentris myso-rensis*, and any similar free-growing, free-rooting plants that it is not convenient or advisable at this time to either move into larger pots or partially reduce the old soil and replace by new.

Large plants of *Ixoras* or other bushy-habited subjects, after having produced their first flowers, may be freely cut back even so far as to reduce them to a third or less of the size they have attained. Where the knife is little used to such things, and they are allowed to go on forming an unlimited number of shoots, these are correspondingly weak, and produce small puny flowers; whereas, if headed back now, at the same time cutting out entirely the small weak growth, they will break strong, making shoots that will flower much better the ensuing spring. By means of an occasional severe cutting-in in this way the plants may be kept for almost an indefinite time in a satisfactory state, producing flowers in greater abundance, and quite as large as younger specimens. After they have fairly broken one-third of the old soil may be shook away, replacing it with new.

Fine *Gloxinias* are now so easily raised from seed, that propagation from leaves is not much practised; but where exceptionally good forms and well-marked colours happen to turn up in this way, or good named sorts are grown, it is advisable to guard against their loss through the winter by raising some young bulbs. The leaves being now firm and well matured are in a right state for the purpose, and there is yet time enough for the young roots to become sufficiently developed to make useful blooming stock for next spring. Flowering stove plants that are required to be used for some weeks at this season in a conservatory should at once be moved there, as after the middle of the ensuing month we frequently experience cold nights. In thus removing

them from the stove or intermediate-house to cooler quarters care should be taken to place them in the closest part of the body of the house, and on no account stand them near the sides where air is admitted that will come directly upon them; neither must they be subjected to cold draughts. Water must also be given very carefully, using no more than will just prevent the young growth flagging. A little shade will in most cases be required. Ferns.—Some of the best and most distinct kinds of Ferns are not so easily increased from spores as the generality of kinds, such, for instance, as *Platycerium grande*, *Brainea insignis*, *Lomaria cycadefolia*, *L. zamiaefolia*, and all the *Gleichenias*; even with the common *Adiantum cuneatum* many growers are not successful, although where the plant is allowed to stand and shed its spores, and the surface where they fall is sufficiently moist and left undisturbed, they generally vegetate in quantity. The want of success, so far as I have been able to make out, is in most cases attributable to the natural habit of the above-named species which disperse their spores almost entirely in a very short time after the capsules or spore-coverings burst. To succeed in raising these Ferns, I have found it necessary to closely watch for the first indication of the spore-coverings bursting, and to immediately rub out the spores from such plants as the *Platyceriums*, or to cut the fronds off the others in this early stage, reducing them to small pieces, and at once sowing them; by this means I have been fairly successful, whereas if left longer in the way that suits the generality of Ferns, I was never able to get a single plant to grow—from the fact, I have no doubt, if I may use the term, of sowing the chaff instead of the seeds, after the latter had fallen. The spores of many of the above plants will about this time be arriving at maturity, and those who intend to increase them by this method should watch closely for the first signs of opening in the spore-coverings, and lose no time afterwards. As to the preparation of the pans in which to sow them, they require nothing different from the common sorts of Ferns—good fibrous peat sifted or rubbed fine with the hand and mixed with a liberal amount of grit or sandstone broken fine, and charcoal or crocks broken small, so as to keep the whole quite open and porous, and standing the pans in feeders containing a little water; by this means the material will be kept moist by absorption, and watering overhead is rendered unnecessary; the latter if practised washes the spores down too deep to admit of their vegetating. *T. Baines.*

FLOWER GARDEN, ETC.

All bedding plants are now making good progress, and the showers which have lately fallen have made a visible improvement on the grass and flower-beds. Geraniums are covering the ground and blooming freely, and will require looking over occasionally and any dead leaves or decayed blooms removed: the tricolors and other variegated sorts grown for their foliage look best with the flowers picked off. The old *Manglesii* makes a fine show either with or without the flowers, and soon fills its allotted space; all it wants is pegging down to keep it in its place, and sometimes pinching out the point to prevent it from rambling beyond its limits. Petunias, Alyssums, Nasturtiums, &c., also require attention to pegging as the shoots advance, and before they get too much entangled. Carpet bedding must have careful supervision, and each sort be kept in its proper place, for effect depends upon the regularity which prevails over the entire arrangement. Attend to staking and training all tall growing and climbing plants. Roses that are blooming freely will be greatly improved by a liberal soaking of soft water with some guano in it, or liquid manure from the tank; any of the over-luxuriant shoots may be cut back, which will regulate and encourage the weak branches. Dahlias, Hollyhocks, and other strong growing things requiring supports want to be frequently examined, in order to prevent accidents to their growing stems. Keep the hoe at work in all places where weeds are beginning to show themselves; the grass should now be kept in the best order possible, and the gravel or grass walks swept or mown as required. *T. Blair, Strabland Park.*

FRUIT HOUSES.

PEACHES AND NECTARINES. — The preservation of the leaves of these trees in a healthy state materially contributes towards perfecting the elaboration of the sap, and the consequent maturation of the wood and buds; see, therefore, that the same degree of attention is bestowed on syringing and watering as was advised to be given to these matters prior to the fruit ripening, and to facilitate the same object keep all lateral growths pinched back to one leaf above each break, and if more growths are laid in over the surface of the tree than actually would be required to produce fruit the subsequent season these should be judiciously thinned out so that those which are retained will have the benefit arising from the free course of air and light about them. If that unconquerable enemy the red-spider abounds on the trees syringe

them occasionally in the evening with strong Quassia water, which will tend in some degree to limit the ravages of this intolerable pest. Towards the end of this, or early in the following month, early forced trees should be fully exposed to atmospheric influences if the construction of the house will admit of its being done, otherwise ventilate the house fully, constantly; and when the natural rainfall is not effective, see that the borders are well supplied with moisture—an arid state of these when the buds are swelling off is doubtless very pernicious in its effects the ensuing year. Trees which are in pots which have been subjected to similar conditions should also be placed outdoors at about the time above-named. It will be an advantage to surround the pots of these at this season with some tan or manure which is free from worms, to prevent the scorching rays of the sun injuring the roots at the sides of the pot; the surface of the soil in the pots should also be mulched with manure. These plants should be fully exposed to sunshine, kept free of insects, the lateral growths pinched-in, and manure-water given to them about twice every week when watering becomes necessary. In houses where the fruit is on the point of ripening pursue former directions which were given under similar conditions as to syringing, stopping, and exposing the fruit, for the purpose of securing high colour. *G. T. Miles, Wycombe Abbey.*

VINES.—Early houses from which the fruit has been cut, particularly if they have been used for bringing on Azaleas and stove plants, should be carefully examined, and if any of the insect pests which usually follow this unsatisfactory kind of forcing have gained lodgment, no pains must be spared in their extermination. Soap, sulphur, Gishurst Compound, and, above all, Read's patent syringe in good hands, with plenty of clear water, will soon bring the most troublesome enemy into subjection. Liberal root waterings will also have a beneficial effect, particularly in cases of red-spider. The sudden changes in the weather and temperature being favourable to scalding in varieties subject to this stoning affection, fire-heat should always be at command to meet any sudden depression, and to maintain a night temperature of 70°, with a little air at the apex of the roof, to admit of the escape of superfluous moisture. Give fire-heat to Muscats now ripening, with a constant circulation of air, but avoid cutting draughts. Aim at a temperature of 70° at night, with a rise of 20° by day; and if the root temperature—one of the great secrets of setting and colouring—has been kept up by fermenting materials or any other means in proportion to the temperature of the house, the Grapes will lay on colour, and shanking will be reduced to a minimum, by the simple fact that roots in a warm medium can take up more food in a given time than they can when struggling for life in a cold one. Pot Vines intended for next year's forcing will have completed their growth. Expose them to all the sun and light, with plenty of air, to ripen the buds. Water with care, and cover up the pots with some non-conducting material, to keep the roots in a moderately moist state. Young Vines planted this spring for cutting back in winter may be allowed to ramble over the trellis. If in outside borders keep the roots near the surface by means of mulching and surface watering. *W. Coleman.*

MELONS.—Where late Melons are wanted another sowing should now be made; but these, like late clingstone Peaches, after having good fruit from the end of April, do not always leave a favourable impression of the flavour to be carried forward. The house in which the late Melons are grown should be light, well ventilated, and efficiently heated with hot water. The pot system having now become so general, and its many advantages so thoroughly appreciated, all who can adopt it will most certainly do so for the production of their latest fruit, which will ripen when the nights are long and cold. If bottom-heat pipes are provided, the pots should be placed within reach of their influence when extra warmth is required for setting and ripening the fruit; but for the present fermenting leaves or tan will produce a moist heat more congenial to the growth of the Melon than that obtained from hot water. Moderately strong growing early kinds, like *Victory of Bath*, *Golden and Turner's Scarlet Gem* are well adapted for late work; the latter, still one of the best scarlets, is excellent for growing on kerbs and shelves, where strong growing kinds would be a failure. Plants in pits and frames swelling off fruit will now take abundance of water at the root. It is not always advisable to water overhead in these structures, where the plants are more subject to canker than in houses, and red-spider is less troublesome. An occasional flooding of the bed with water at a temperature of 90°, without wetting the foliage, about 4 P.M., with a closing temperature equal to that of the water, will produce an atmosphere highly favourable to the rapid development of the fruit, which should be elevated on pots level with but not above the surface of the leaves, as some kinds are liable to scald if fully exposed to the direct action of the sun. *W. Coleman, Eastnor Castle.*

HARDY FRUIT GARDEN.

The great scarcity of fruit of all kinds will render increased vigilance necessary to preserve what little there is from the ravages of birds, which, owing to the mildness of the winter, are this year more than usually numerous, and particularly is this the case with those bold hardy depreicators, the blackbirds, that appear to put all ordinary means of protection at defiance, so persevering and successful are they in finding a way through nets or in pressing them down by their weight sufficiently low or close to the tempting Cherry or Strawberry to reach the fruit between the meshes. To obviate this what nets are used should be of fine make and properly supported by running rods, string, or wire strained tight from stake to stake placed at about 10 feet apart down the centre of each bed where these only consist of three or four rows, but in larger plantations it is better and more convenient for gathering if they are placed at a sufficient height for a man to pass under. As regards Cherries on walls the best way to keep the nets projecting at a proper distance is to run pieces of string from top to bottom at 10 or 15 feet apart, and to strut them out at the middle by the use of slit or forked sticks, by which means the fruit can be gathered daily as required, and the net dropped again in its place. When struts alone are used most of them fall or become displaced at each picking, and there is consequently much loss of time in putting them back in position again. Although an outlay at first, by far the safest and most economical way of protecting Gooseberries and Currants is to use fine-meshed galvanised wire netting, which with care will last a lifetime, whereas that made with string soon rots, and is a constant source of expense without being at all efficient. Till I obtained some of this I had much difficulty in coping with blackbirds, but by surrounding the bushes with wire netting we have always plenty of fruit as long as it will hang on, which in favourable seasons it continues to do up to a late period. For single full-sized bushes from 8 to 12 feet lengths are required to envelope them, but the best plan is to run the wire along each side of a row, or encompass the quarter in which the Gooseberry and Currants are growing, and then strain a piece of ordinary net over the top. Most fruit trees appear to be running riot this season, owing to the lightness of their load, and it will therefore be necessary to go frequently over them to pinch-in any breastwood they may be forming, and to lay in and regulate such as may be required for filling vacant spaces, which, unfortunately, are but too common on both Peach and Apricot walls. Apples and Pears must be attended to in like manner, in order to admit plenty of light and air round about the spurs, and assist them in developing plenty of fruit-buds. Grafts of the above will now have advanced to that stage of growth as to require the removal of the ligatures used for tying them in, for if these remain on after this time the rapid swelling of the scion soon buries them beneath the callus formed, and when this is allowed to take place the union is seldom neat or perfect. To render them safe from being blown out by wind, see that they are made secure to sticks tied to the branches for that purpose, as the next two months or so will be a critical time for them, owing to the increased amount of leafage they will be making from day to day, and the insecure manner in which they are united to the stocks. The present is a favourable season for putting in buds of all kinds of fruit trees that are increased by that means, such as Cherries, Peaches, Nectarines, Plums, and Apricots, and where Apples or Pears have failed, or it may be desired to introduce any choice new kind, they, too, may be worked now just as successfully as any of the foregoing. In carrying out this operation the chief thing is to secure buds from wood in a semi-ripe state, and such as are fat and plump, and if these are taken off and inserted without bruising the bark, scarcely one in a hundred will fail if properly tied in before they become withered and dry. The mild winter has been exceedingly favourable for Figs, which are showing unusually heavy crops of fruit, and that this may have the full benefit of sun and air to ripen it, all superfluous strong wood, such as is generally formed in the body of the trees at this season or springs from their base should be removed, but it is not advisable to stop or interfere with the points of the shoots, as that induces the fruit to start, and become too prominent in the autumn, and which the first severe frost will destroy. *J. Sheppard.*

The following anecdote is narrated by the late Sir John Malcolm, in his *Sketches of Persia*:—"A breakfast was given to us at a beautiful spot near the Hazār Bāgh, or thousand gardens, in the vicinity of Shiraz, and we were surprised and delighted to find that we were to enjoy this meal on a stack of Roses. On this a carpet was laid, and we sat cross-legged, like the natives. The stack, which was as large as a common one of hay in England, had been formed without much trouble from the heaps of Rose leaves, collected before they were sent into the city to be distilled, *Rivers' "Rose Amateur's Guide."*

THE
Gardeners' Chronicle.

SATURDAY, JULY 14, 1877.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY,	July 17	{ Royal Horticultural Society: Meeting of Fruit and Floral Committees, at 11 A.M.; Scientific Committee, at 1 P.M.
WEDNESDAY,	July 18	{ National Carnation and Picotee Society and Cut Rose Show at the Royal Aquarium, Westminster (two days)
THURSDAY,	July 19	{ Colchester and East Essex Horticultural Society's Show.
FRIDAY,	July 20	{ Cleckheaton Agricultural and Floral Show.

IT has been said, and with as much truth as attaches to similar general statements, that every child is a born naturalist; at any rate, a very large proportion of children are so endowed. And what do we adults, in our superior wisdom, do under such circumstances? Why, stamp out the germs of natural knowledge as if they were so many Colorado beetles. We most of us think or act as if we thought the works of man as of far more importance than the works of the Creator. The child has a truer instinct, but we do our best to crush it. Of course there is not the smallest possible doubt of this, and if proof were wanting it might be found in the discussion in Parliament and in the comments in the daily press on the EDUCATION QUESTION. Let it be understood we are speaking particularly of the elementary education of the children of the working classes in purely secular matters, and of the lower grades of the working classes, those whose means do not permit them to expend much money on the education of their children. Those children, it is to be presumed, will have to earn their daily bread by the sweat of their brow. On all accounts it is desirable to make them upright, honest, hard-working, in a word useful citizens. By so doing—omitting all higher considerations, which are beyond our province—we should do our best to promote the welfare of the child and the advantage of the nation. Well, how do we set about all this? We teach the child to read and write—we can do no less, so much is absolutely essential—a knowledge of the multiplication table and of the first four rules of arithmetic are scarcely less essential. These things must be taught, they are the keys of all future acquirements, the stepping-stones to all further progress. Supposing all this done and the general principles of religion and morality inculcated—principles even more essential than the three R's—what next ought to be done? Here, as it appears to us, is the point whereat our educational schemes break down, and where the natural instincts of the child are often most cruelly suppressed and perverted, instead of being cherished and directed. Take the study of history, what do we find? What was our own experience in higher class schools than those we are now alluding to? History, as taught, was in the main an affair of dates and battles. Little or no attempts were made to show the bearing of the history of the past on that of the present—we were left in entire ignorance of the history of our own times—not made aware in any sense that we were ourselves living in the midst of what would in a few years time be history. So with geography—the capitals of Europe, the rivers on which they are situated, the principal mountain ranges, were all taught perfunctorily and got by rote without the slightest real personal knowledge being obtained. It is not necessary to give further illustrations. Every man or woman who has got to adult age will recognise the general truth of our statement. How is a better system to be brought about? The child here is our teacher—watch his eager interest in the animals that fall under his notice—see the excitement and interest with which he gathers huge handfuls of wild

flowers. Why let all this keen apprehension run to waste—why not direct it, guide it, make it the basis of our instructional efforts? The observing faculties are those which are most highly developed in childhood, the reasoning faculties assume their fullest development much later, but the two are, or should be mutually interdependent. We want to control the child's apprehension and direct his intelligence, to make him observe—not more quickly, in most cases he does that sufficiently already, but more accurately and systematically, so that when he gets older and his reasoning powers become more matured, he may have a solid basis of self-ascertained fact as well as of second-hand memory whereon to base his reasoning. For

trained children? Teach them to observe properly, and especially to discriminate carefully, and then there will be no fear, as there otherwise will be, of ladybirds or other useful insects being destroyed with the noxious ones as they now are. If children were trained to observe birds and bird-habits, to note which were the farmer's friends and which his enemies, surely good would result. Teach the child something of the reason why he is called on, or will be as he grows older, to do certain work in a certain manner. Surely the work of the garden will be all the better done if an intelligent appreciation of the why and wherefore be taught. Even for the matters of domestic economy and cookery, which very properly were introduced

FIG. 5.—DIOSCOREA BULBIFERA.

elementary schools, especially in country districts, the study of the plants, insects, the birds, the animals of the district, form, as we believe, the best educational training for the majority of children once the three R's are mastered. In studying geography we would commence with the hills and dales, the railroads and rivers, the marshes and woods of the particular district in which the school was situated. The children should be shown geology in progress after a shower, in the drying up of a puddle, or in the effect of frost or wind. If the children are to become gardeners, or farm labourers, or carpenters, or blacksmiths, what possible better preparation could there be than elementary instruction in natural science? Who would do such efficient police service, say in the matter of the Colorado beetle, as well-

into a recent debate on education in the House of Commons, a training in the principles of natural history and chemistry forms, together with arithmetic, the best preliminary preparation.

For the general culture of the faculties, or as a preparation for the general business of life, there can be no better preparation than a sound training in the elements of natural science, while even in the matter of moral training we submit that the reverent study of GOD'S works must be far more beneficial than the study of man's words, however full of wisdom they may be. Oh! but, some may say, how is all this to be accomplished? Your theories may be unexceptionable, but how do they work in practice? We will cite, by way of reply, only one instance—one with

FIG. 6.—DIOSCOREA BULBIFERA.

which the older readers of this journal are familiar—that of the village school established by the zeal and wisdom of the late Rev. Professor HENSLAW. We cannot all have the same physical strength and mental power that he had, but we may all in our degree imitate his system of educating and training the children of the labouring classes of the rural districts.

WE figure a very old garden plant—it was introduced as long ago as 1692—for the sake of illustrating a very beautiful and readily grown climbing plant. *DIOSCOREA BULBIFERA* (figs. 5 and 6), is, like its congeners, of twining habit, with bold foliage, and elegant drooping racemes of greenish flowers. In the axils of the leaves in the species figured are formed small fleshy tubers by means of which the plant is propagated. They were removed before the specimen was sent to the artist for figuring, hence they do not appear in his drawing. We saw the plant lately in the collection of Mr. W. BULL. The tuberous roots of many species are known as Yams, and largely cultivated for esculent purposes in the tropics. The Chinese Yam, *D. batatas*, a few years ago recommended as a substitute for the Potato, has lost what reputation it had, and it is rarely met with now; though, should Potatoes again become scarce, substitutes will have to be employed, and this Yam is by no means the worst of the many proposed substitutes.

— We received a few days ago from Mr. JOHNSTON, gr. to the Earl of STRATHMORE, Glamis Castle, some berries of LADY DOWNE'S GRAPES, which were ripe in August, 1876, and cut and bottled in the usual way in the first week of January last. The stalks were quite green and fresh, and the berries as plump as could possibly be desired, while the flavour was excellent. Considering the length of time they had been kept, these were the finest of their kind we have seen. As Mr. JOHNSTON observes, there can be no doubt about Lady Downe's being the best late Grape we have. Mrs. Pince's Black Muscat, ripened and treated in the same manner, does not keep well at Glamis after April, but Royal Vineyard and Alicante keep well till May.

— It is proposed to construct a PNEUMATIC RAILWAY from SOUTH KENSINGTON STATION to the ROYAL HORTICULTURAL SOCIETY'S GARDENS and Albert Hall. The rise will be 1 in 48 to the Hall. So then our horticultural friends will be blown through a tunnel to their destination. Engineers speak very favourably of the project.

— A committee, consisting of Sir WALTER TREVELIAN, Athenaeum Club, Pall Mall; Sir JOSEPH HOOKER, Kew; Colonel TREVOR CLARKE, Welton Place, Daventry; Dr. MAXWELL T. MASTERS, 41, Wellington Street, Strand; R. MARNOCK, Esq., 20, Spring Gardens; and D. WOOSTER, Esq., 18, The Terrace, Kensington Gardens Square, has been formed for the purpose of purchasing the only existing portrait of the late JOHN CLAUDIUS LOUDON, whose manifold services to agriculture and horticulture should insure the gratitude of horticulturists for many generations to come. An excellent portrait was taken by Mr. LINNELL a few years before Mr. LOUDON'S death, and this portrait it is proposed to purchase and present to the Linnean Society, to be hung in the Library of that body. We should prefer that the portrait, when obtained, should be made over to the trustees of the Lindley Library, to be hung in the Council-room of the Royal Horticultural Society, which appears to us a more appropriate place of the two for the reception of such a portrait; but we are told that there are sundry good reasons why the Linnean Society (of which Mr. LOUDON was a Fellow) should be selected. Any member of the committee will be glad to receive contributions towards the object in question.

— The third number of the *Journal of Forestry* is before us, and amply bears out the favourable opinion we expressed as to its predecessors. In manner, matter, and method this journal is good. In the present number are contained, *inter alia*, articles on the timber supply of America, in which the author assumes that if no remedy be applied to ensure a supply for future generations, the timber supply in the Eastern States and Canada will be totally ex-

hausted in fifty years, and a systematic plan of forest conservancy, as adopted in Germany, is recommended as essential. Mr. BURROWS' paper on coppice wood, as managed in Kent, is likely to be very useful. In no part of the kingdom that we know of are coppice woods better managed than in Kent, and in none is it more profitable. The Rev. Dr. BROWN gives an account of the course of study in the Forest School of Carlsruhe. Mr. KAY, of Rothsay, describes how, in the western islands of Scotland, and with the aid of his transplanting machine, he planted a number of Sycamore trees averaging from 25 to 30 feet in height, as well as (in former years) Oaks, Limes, Yews, Laurels, Elms 30 to 40 feet in height—in all about eighty trees, varying from 20 to 45 feet high. The trees were in no way prepared beforehand, and up to this time only two absolute failures have occurred. The correspondence is varied, and it is to be hoped the editor will know how to prune and cut out personalities. It is rather late in the day to give a review of "Senilis" on *Pinacea*, the author of which wild book has gone to his rest some years since.

— In the last number of the *Revue de l'Horticulture Belge* M. A. DE SMET calls attention to the following varieties of *Echeveria* adapted for outdoor cultivation for edgings, &c. :—

E. FARINOSA, a form covered with mealy pubescence, the lower leaves rose-tinted, the latter tint becoming enhanced by exposure to the sun.

E. GLAUCA, *E. BRACTEOSA*, *E. GLOBOSA*, with rosettes of leaves of a pale blue colour edged with white. It belongs to the same section as *E. glauca*, but is superior to it.

E. IMBRICATA, a form with orbicular mucronate leaves. The young leaves are glaucous, passing into rose, and ultimately into bronze. This is a very distinct form, of medium size.

E. IMBRICATISSIMA, a form with nearly tubular leaves closely compacted, carmine-red in the centre and at the point, edged with silver, forming a splendid variety, resembling at a distance a Dahlia tipped with silver. This was sent out by M. DE SMET.

E. METALLICA, *E. METALLICA GLAUCA*, *E. SCHEIDCKERI*, and *E. SCAPHYLLA*, the latter a form with thick concave bright green leaves.

— The HOP PLANTATIONS around Ashford, according to the *Maidstone and Kentish Journal*, have been doing famously during the week ending July 7. The leaves of the plants are of a healthy colour, and the bine vigorous, with the lateral shoots pushing forward rapidly. The ground has been copiously irrigated, and having been well worked, cleaned, and manured during the dry weather, the effect has been surprisingly beneficial. The prospects of the crop improve greatly, and although there is a certain portion of the growth which no favourable influences can make productive, yet the general result will be far more satisfactory than was at one time thought possible.

— In a recent issue Mr. WORTHINGTON SMITH announced the discovery in some Potatoes grown at Chiswick, and laid before the Scientific Committee of the Royal Horticultural Society, of the same appearances as he had met with last year in Potatoes grown in the same garden. It will be remembered that the appearances were somewhat different from the POTATO DISEASE as ordinarily seen, so much so that when first noted at Chiswick (chiefly in the American varieties) it was considered to be a new disease. Others maintained that it was the old disease known as curl. These statements were followed by the discovery in these Potatoes of globular bodies, considered to be the resting-spores (which may be compared roughly with the seeds) of the Potato fungus, and of the smaller bodies known as antheridia, and which may, for the sake of illustration, be compared to the pollen cells of a flowering plant, and by means of which the resting-spore becomes fecundated, and enabled, after a period of rest, to germinate and produce new fungus threads, or under other conditions to break up into a number of fine movable spores or zoospores. Mr. SMITH'S discovery was challenged, and by no less an authority than Professor DE BARY; but Mr. SMITH'S subsequent researches served, in the opinion of those on this side of the Channel most competent to judge of so difficult a matter, to confirm his original statements. Professor DE BARY, we believe, is still of opinion that Mr. SMITH'S conclusions are erroneous, and that the

structures seen belong not to one but to two or three distinct fungi. We have no desire to comment on this matter now further than to say that our examination of the Chiswick tubers a few days since was entirely confirmatory of Mr. SMITH'S observations. We had no difficulty in seeing the young resting-spores (oogonia), the smaller antheridia, the male organs, the zoosporangia, or cases containing movable spores, and the conidia or bud-spores, with, of course, the peculiar spawn-threads of the Potato fungus.

— In reference to the paragraph published at p. 791 of our last volume, referring to the SLOW INCREASE OF TULIPS, which, in some cases at least, has been observed, Mr. R. PARKER informs us of a much more striking case of obstinate refusal to increase and multiply than that above cited. Mr. H. GOLDHAM, of Mitcham, a name well known to Tulip growers of the South, has grown for the past thirty-five years and has still in his possession a bulb of the variety called Rose Lac, from which he has not obtained any offsets. On one or two occasions only, during all this period, has there been an indication of an abortive attempt to form offsets. The plant has nevertheless continued to grow and bloom healthily during all this period.

— At the June exhibition of Roses and Strawberries, held by the New York Horticultural Society, Mr. WILLIAM SMITH, Morrisania, New York, is reported to have shown some monster fruits of his new seedling STRAWBERRY, PRESIDENT LINCOLN, the largest measuring over 11 inches in circumference. Ten berries weighed over 1 lb., and its flavour was pronounced excellent by the judges.

— Looking round Mr. BULL'S nursery the other day, we lighted on a number of plants of a dwarf Rose, a very prickly fellow, with peculiar foliage, four pairs of closely set leaflets, with an odd one at the top, all deep green, regularly crenated at the edge, rough on the surface, like a Potato leaf, and the flowers 3 inches in diameter, of a rich rosy lilac, the petals flat, a little recurved at the margins—such a beauty and so sweet. It was the *ROSA RUGOSA* of Japan, lately reintroduced under the name of *R. Regeliana*. It is quite hardy, and though not a florists' flower it is very beautiful, and should be looked after by the hybridists. At Cliveden a white variety is grown with the ordinary form.

— You want an EDGING FOR YOUR ROSERY?—well, if your soil and climate are good try Rose de Meaux, or the little Fairy Rose, but as these will only do well in exceptional positions then use the double Scotch, and keep it well clipped. There is a very beautiful rosette at Dr. INGLEBY'S seat at Valentines, near Ilford, and it is bordered with the Rose in question, and nothing can be more satisfactory. The rosette in question is of oblong shape, bounded by four Rose beds trained over wire trellises breast high. By a happy thought or fortunate accident a few wild Briar Roses are interspersed, and most beautiful they look even amid their more highly cultivated kindred. What a compliment to the wild white Rose, and to the single Boursault, which also figure there, and yet it is true. The hedge in question encloses a number of beds filled with dwarf Roses, and in the centre is a pavilion draped with climbing Roses, enclosing a bed of Moss Roses. On the adjacent wall Mr. EARLEY has planted the Macartney Rose. The whole garden is old-fashioned, but full of interest, as a garden should be. Beauty without interest is like a pretty doll in a hairdresser's window.

— In Paris the work of embellishment from a horticultural point of view is still carried on with great energy. From the *Bien Public* we learn that no fewer than five new gardens will shortly be opened to the public. These, like most of the open spaces within Paris, are of small extent, but they will be all the more welcome in a city where the people pass nearly all their waking hours in the open air. According to the same authority Paris now possesses seventy-eight parks, squares and gardens, forming a total area of about 142 acres. This of course does not include the relatively large, as compared with London, open spaces afforded by the shaded boulevards; but altogether the total breathing grounds

of Paris are much smaller in relation to the population than those of London. And as regards the trees of Paris, although we of this generation at least can never hope to see the streets of London so generally planted as those of Paris are at the present time, we may expect to see as good or better trees in London than those in the boulevards of Paris at the present date. Generally speaking the trees of Paris are disappointing, and, from well-known causes, do not exhibit great vigour. In a word their condition seems to warn us against attempting to imitate Parisian boulevards in our narrow streets, where trees have no chance against the many unfavourable conditions. But where there is sufficient space in London for trees, and where their management is entrusted to competent persons, we believe they will succeed better than in Paris.

— It will be remembered that we have frequently had occasion to mention a PINK SPORT FROM GLOIRE DE DIJON, of which, through the kindness of some of our correspondents, we have now seen several instances. The full history of this Rose has been given at various times in our columns, and was summarised in a paper read to the Scientific Committee of the Royal Horticultural Society and printed in the last volume of the *Journal* of the Society with a coloured illustration. It is then with no little interest that we learn from Dr. SCHÜBELEK'S last volume on the Vegetation of Norway, that a plant of Gloire de Dijon growing in a garden at Christian'a, and grafted on the Brier, was observed to produce a pretty dark red coloured Rose, no doubt similar to that which has been observed here.

— Our next issue will contain, in addition to the ordinary matter, an account of the grounds at CLIVEDEN, the seat of His Grace the Duke of WESTMINSTER, illustrated with several beautiful wood engravings illustrating the exquisite scenery of this charming domain.

— How much remains to be done in all tropical and sub-tropical countries, and indeed one might say in all countries, beyond simply collecting specimens of natural history, is suggested by the interesting facts observed by the more intelligent of travellers in short excursions and under unfavourable conditions for working out their full import. When naturalists tire of describing plants and animals from dried or stuffed specimens, and take more interest in the life history of all organisms, we shall doubtless hear of expeditions to their various native countries, where alone such investigations can be successfully and profitably conducted. Half matured theories will be upset, and valuable and reliable data for a correct appreciation of the laws of Nature will accumulate, until we shall be in a position to understand something of this difficult subject. In a letter published in the *Flora*, 1877, p. 239, Mr. F. MUELLER, writing from Blumenau, province of Santa Catharina, Brazil, gives a brief account of a trip to the highlands of the province, and the western side of the Sierra, in the region of the sources of the Uruguay. One of the most remarkable facts that came under his observation was the number of plants with HYGROSCOPIC BORING SEEDS and seed-vessels, though he had seen none on the eastern side of the Sierra. More than a dozen different grasses, exhibiting this property, were noted on a short visit, among them some exceedingly curious and diverse from those described by FRANCIS DARWIN. In a species of Violet having cleistogamous subterranean flowers, the open flowers appeared to be equally or more fertile than the closed ones.

— In Northern FRANCE, as in this country, the SPRING CROPS were very backward; and fruit, such as Pears, Cherries, and Plums, judging from limited observation in the vicinity of Paris, very scarce. As an instance of the lateness of the flowering of Apple trees, we may mention that we observed at Orsay, south of Paris, on June 10, a small orchard of Apple trees of one variety, the blossom of which at that date had scarcely attained its full beauty. It was certainly a very late variety, the name of which we were unable to ascertain.

— We were lately visiting some gardens at a short distance south of Paris, in some of which it was quite disheartening to see the devastation caused by the

larvæ of the MAY-BUG or COCKCHAFFER. Whole quarters of Potatoes, Kidney Beans, and other crops, were completely destroyed, resulting in a serious loss to the small owners. For years the French have been waging constant war with the perfect insect, and in some districts the children of the poor earn many shillings by capturing them in large numbers, for which they are paid at a certain rate. In spite of this activity, the cockchafer propagates so rapidly, that in some seasons and districts it is more destructive perhaps than all our insect foes in England collectively.

— IMPATIENS JERDONÆ, an extremely rare and pretty species, is flowering in the Begonia-house at Kew. It is epiphytal, with tufted, short, here and there constricted stems. The leaves are ovate, few, and confined towards the growing point. The flowers are of peculiar conformation, coloured with crimson, yellow, and green; the anterior petal is crimson, and consists entirely of a large, curved, and compressed sack—its most attractive feature. It was first introduced to Kew by Mr. McIVOR, who sent the curious-jointed stems from the Neilgherries, and the present plant was contributed by Mr. W. BULL. Some difficulty is generally found in the cultivation of this species, probably from want of suitable position. Neither in the greenhouse nor stove will it continue to do well, but requires an intermediate degree of moisture and temperature. It has been one of the specialities of Messrs. E. G. HENDERSON, who for a long time kept up a stock for trade supply. It may be grown either in pots or baskets, but should be kept near the glass.

— In spite of the very large extra number of this journal which was published last week, together with a large coloured plate, the supply has proved much inferior to the demand, and many must, we fear, be disappointed in not being able to procure a copy.

— HOODIA BARKLYI, a new and quite distinct species, is flowering in the Royal Gardens at Kew. The stems of the three recognised species (trusting to figure for *H. Carreri*) are extremely similar, though the present is apparently smaller in habit of growth than *H. Gordonii*, which flowered at Kew some time ago. The present species is conspicuously distinct in having a cyathiform corolla. The first flower open on this plant had a corolla composed of four petals.

— In an address to the Horticultural Society of Berlin on walking-sticks, Dr. ASCHERSON stated that Dr. BECCARI had discovered the origin of THE RAJAH CANES OF BORNEO to be the aerial roots of a Palm, *Eugeissonia minor*, Becc. Another kind of stick commonly used in Germany, and called Russian Roots, is supposed to be *Acer campestre*. They were formerly much used for pipe-stems. Dr. ASCHERSON also exhibited a fine dark brown stick from a variety of the Date Palm, which only grows in the oasis of Jupiter Ammon. It has dark brown midribs, and is known by the name of *Phoenix dactylifera Ammonensis*. It was also shown at the Amsterdam Congress.

— Some few years ago (*Botanische Zeitung*, 1873, pp. 529 and 545) BRIOSI sought to show that the first visible product of assimilation in the Musaceæ was not starch, as in other plants, but oil. Dr. E. GODLEWSKI (*Flora*, 1877, p. 215) professes to have wholly disproved this statement. By isolating portions of healthy young leaves in an atmosphere charged with 6 to 8 per cent. of carbonic acid gas he was able to observe or determine abundant formation of starch in the grains of chlorophyll. He also succeeded in detecting starch in the chlorophyll of young leaves growing in the ordinary atmosphere, especially in the evening after a hot day.

— The preparations for the INTERNATIONAL HORTICULTURAL EXHIBITION to be held at Carlisle next September are now being rapidly elaborated. The exhibition will take place on the extensive meadows called "The Saucerics," which stretch from the ancient battlements of Carlisle Castle to the green banks of the River Eden, a few miles from its confluence with the Solway Firth. The accommodation for fruits, plants, flowers, vegetables, &c., will be considerably larger and more convenient than that

prepared for the last International Show at Dundee. The interior arrangement will be somewhat as follows:—The fruit will be placed on tables in a marquee 400 feet long and 30 feet wide. The plants in pots will occupy the centre in a circular pavilion 100 feet in diameter, and other marquees extending to 500 feet in length and 40 feet wide. The vegetables, cut flowers, dinner-table decorations, &c., will be arranged in marquees 300 feet long and 40 feet wide, and the large meadows exterior to the marquees (which will be properly enclosed) will be occupied with collections of Conifers and ornamental shrubs and trees, as well as horticultural buildings and their appliances, rustic summer-houses and chairs, garden fountains and vases, ferneries and aquariums, iron fencing, gates and chairs, &c. Carriages will have a ready access to the show ground, and can set down their occupants at the covered entrance to the marquees, which will be constructed by UNITE & SONS, of Paddington, and will be perfectly water-tight. The judges have all been appointed, and exhibitors will be pleased to learn that the duties of this laborious and somewhat thankless office have been entrusted to gentlemen of undoubted skill and experience. The management of the show has been placed in the hands of Mr. WILLIAM THOMSON, of the Tweed Vineyards, Clovenfords, who will be assisted by an efficient executive committee. The subscription list is being daily augmented with new names, and the committee, being now satisfied that the show will be a great success, are rapidly completing their preparations.

— LILIUM CORDIFOLIUM is about to flower at Kew, and we believe for the first time in this country. It is nearly allied to *L. giganteum*, but is not nearly so fine from a horticultural point of view. The flowers are only 4–10 in comparison with 12–20, and besides are smaller in size, with narrower segments. It is certainly a more difficult plant to manage.

— Mr. B. S. WILLIAMS has again achieved a genuine success at the OPORTO HORTICULTURAL SHOW, having succeeded in carrying off the only gold medal awarded, for six new plants; the 1st prize (silver medal), for ten Orchids; 1st prize (silver medal), for three new Dracenas; also a prize for his four horticultural works—viz., *Stove and Greenhouse Plants*, *Flowering and Foliage Plants*, *Ferns and Lycopods*, and *Orchid Grower's Manual*. The prize of honour was also unanimously awarded to him for the best collection of plants at the show. This was presented by the Municipality of Oporto. It is a superb silver cup, richly engraved and embossed, and valued at £50. The group of plants sent included Orchids (over twenty in number), Pitcher plants, Dracenas, &c.

— We hear from Mr. CROUCHER that AGAVE MIRADORENSIS, syn. *A. Vanderwinni*, and *A. Kelackii*, will shortly be in flower in Mr. J. T. PEACOCK'S collection. It belongs to the Candelabra-formis section, and has a spike 12 feet high, the growth of a month.

— According to Mr. SHIRLEY HIBBERD the number of new ROSES introduced from France in 1864 was twenty-two, and in the succeeding years the sale was as follows:—1865, sixty-eight; 1866, fifty-one; 1867, sixty-three; 1868, seventy; 1869, fifty-seven; 1870, seventy-five; 1872, sixty-six; 1873, forty-three; 1874, fourteen; 1875, fifty-five; 1876, fourteen; and 1877, thirty-eight. English raisers in the same interval have sent out in 1864, two; 1865, four; 1866, four; in 1870, three; 1872, eight; 1873, two; 1874, six; 1876, thirteen; and in 1877, two. The total number being for France 536, for England only forty-four.

— Many choice plants are in flower on the ROCKWORK at KEW. *Meconopsis Wallichii* is in fine condition, appearing perhaps at its best. *Anemone obtusiloba*, not known to be in cultivation elsewhere, is conspicuous with a number of white flowers. It is a native of the Himalayas, whence it was introduced many years ago by the Horticultural Society. The leaves are ample in breadth, and the flowers grow several together on short pedicels within a leafy involucre. *Dianthus superbus* is in great beauty; the flowers are flesh-coloured, and divided almost entirely into fringe. *Orchis foliosa* is flowering well and

strongly; it grows up year after year without trouble, as do several others of the hardy Orchidaceæ. *Cypripedium spectabile*, the Mocassin flower, is quite lovely among the Ferns, where its requirements are perfectly suited. *Arisema concinnum* has been out all winter; it has thrown up a strong scape, but the spathe is not so prettily marked as when grown indoors. *Delphinium cashmirianum*, introduced not long since, is really an ornamental plant, being dwarf in habit, and bearing large blue flowers. *Primula sikkimensis* has been flowering finely, so also has *P. luteola*. *Phlox ovata* is a fine broad-leaved species with pink flowers, well worth growing. The silvery *Edelweiss* of the Alps—*Leontopodium alpinum*—is coming into flower. Conspicuous in addition to the above are *Pentstemon glaucus*, *P. puniceus*, *Erodium Reichardi*, and the rare *Wulfenia Amherstiana*.

BRITISH GARDENERS.

THOMAS BANNERMAN.

The subject of our present note was born in 1840, in Golspie Tower, Sutherlandshire, a village near Dunrobin Castle, the seat of the Duke of Sutherland. At the age of 13 he entered Dunrobin Gardens under Mr. McDonald, and was there for some time employed in the flower and kitchen gardens, after which he was moved to the houses to look after the fires, &c. While at Dunrobin he had a good opportunity of acquiring a sound knowledge of outdoor gardening, under the able superintendence of Mr. McDonald, who always took great interest in imparting instruction to his juniors. He remained there until November, 1857, when he was recommended by Mr. McDonald to the late Mr. Fleming of Trentham, which gardens he entered in the beginning of 1858. Here, after working a few weeks in the kitchen garden, he was moved to the Melon and frame ground, where pot Vines, succession Pines, Melons, and Cucumbers, &c., were largely grown. Mr. Fleming considered this one of the best charges for a young man, and Mr. Bannerman was entrusted with it for eighteen months, and was then moved to the late vineries, and soon after took charge of the early ones also. "I took a great interest in this department, and there were some very fine fruit grown under the management of Mr. Henderson, who was head gardener at Trentham at that time."

In 1861 he was recommended by Mr. Fleming and Mr. Henderson to Lord Bagot, and he went to Blithefield on October 14 of that year. Here the vineries were in such a state that it was found useless to attempt to grow Grapes until the borders were renewed, notwithstanding that his employers were anxious to have a supply of good Grapes. The early vinery was necessarily forced, owing to the obligation to force many plants for cut flowers, and a very poor lot of Grapes was the result.

"I cut the last bunch," he writes, "out of the early house on June 8, and at once commenced to make my first Vine border. I had the house well shaded with mats, as the Vines were quite green in leaf. I took them up, made new drainage, and replanted them in a new border, of which 3 feet was inside and 3 feet outside. I kept the house for ten weeks afterwards at about 65° at night, with a moist atmosphere; the Vines soon commenced to make growth, and by the autumn the border was filled with fresh roots, and the following year we had a very fine house of Grapes ripe at the end of May. My employers were so satisfied with the result, that they had three new vineries put up that autumn, and gave me permission to renew all the other houses. The following year I had them all reheated and new borders made, and the result has been so satisfactory that his lordship has since put up two other ranges of forcing-houses."

Of the success he has had in fruit growing Mr. Bannerman remarks that the gardening public will be the better judges. Suffice it to say that during the thirteen years he has been an exhibitor he has taken over 600 prizes for fruit at the London and local shows.

"I have much," he adds, "to be grateful for in respect to the confidence reposed in me and the kind-

ness shown to me by both Lord and Lady Bagot, by whose desire we are always adding to and improving the gardens."

Home Correspondence.

Vegetable Marrows.—These are largely grown for the town market in the Fulham district. One grower has this season over ten acres of them, and the growers generally consider that they pay nearly as well as Cucumbers. The first sowing is made early in February, and over a thousand yards of framing is devoted to them. As soon as they are fit to handle they are potted into 4-inch pots; in a few days they receive as much air as the weather will permit, stocky plants being preferred. These are planted in frames in the following manner:—Trenches 2 feet wide and 18 inches deep are thrown out, and filled with fermenting manure well trodden down; 6 inches of the soil is levelled back on the top of the manure, and the frames arranged on the top of the trenches; the plants are planted 4 feet apart, and some short litter spread over the surface of the beds—it helps to retain the heat and moisture. They are as carefully attended to as Cucumbers. The tops are pinched over or tied, carefully ventilated, and well covered up at night till there is no danger from frost. This planting generally comes into use about the first week in June, the frames are

now raised off the ground and the glass taken off during the day; by-and-bye it is altogether dispensed with, and the plants allowed to ramble at will. The second sowing is made about March 1, and planted under hand-glasses early in April. The rows are marked off 12 feet apart and the plants are planted 5 feet apart in the rows; holes are dug out large enough to contain a bushel of hot manure, which is covered up in the form of a hillock on which the plants are planted and a hand-glass put over them. A mat is allotted to each glass, and they are covered up every night till all danger of frost is over; the 12 feet spaces between the rows are planted with Cauliflower plants or sown with Radishes. When these are cleared off the surface of the soil is covered with littersy manure. Marrows luxuriate in a moist, rich soil. The last sowing is made about the end of March, potted off and grown into stocky plants, planted as before, but without hand-glasses; about the end of May and well into June, as ground becomes vacant, the spaces between this planting are sown with Radishes: the long white seems to be the variety generally grown. It is no unusual sight to see as many as two or three wagonloads going from one grower's on a market night. Their cultivation being so easy, any one with a few spare yards of ground and a barrow-load of manure may have them in abundance; they do well to cover the rubbish-heap during the summer, as they like to ramble about. Apples being likely to be scarce, I may notice that the Marrows make a good marmalade or preserve, peeled, cut into pieces,

cleaning out all seeds, adding about the same weight of sugar, a few bits of orange-peel, lemon-peel to flavour, and enough golden syrup to give a nice colour. *E. W.*

Cucumber Flowers with Leafy Calyx.—We have those at times something like the one you give on p. 822. We have also had many Melons this spring with proper leaves, sometimes above and sometimes below the proper female flower on the Melons. I have observed, too, that the flowers with three leaf appendages have remained longer on the fruit than those which had none. A Melon of Sutton's Horticultural Prize—along-shaped, rather Gourd-looking Melon—of excellent quality, however, kept one of those appendages fresh and green until the fruit were almost ripe. We do not seem to have any very good specimens of Melons thus furnished left at present. Should any good shows occur, and you care to have a Melon with such an appendage, I shall send it up at once. *D. T. Fish.*

Bougainvillea speciosa.—With this I send for your inspection a small box of *Bougainvillea speciosa*. It may be interesting to some of the readers of the *Gardeners' Chronicle* to know that the *Bougainvillea speciosa* will grow and bloom to perfection in a conservatory or cool-house. The plant that I have cut the enclosed specimens from was planted in the conservatory here six years ago in a well-prepared border. Two years after it was planted it reached the apex of the house, and began blooming. It has bloomed most profusely every year since, but I think it is finer this year than ever I have seen it. I know of no plant better adapted for a conservatory climber than *B. speciosa*. It retains its foliage all the year, and invariably lasts in flower over three months. I may further add that the conservatory here is about 22 feet high, and the roof is glazed with Hartley's patent fluted glass. *A. Ingram, Alnwick Castle Garden.* [Richly coloured, Eds.]

Triteleia laxa.—Among hardy bulbous-rooted plants now flowering in the herbaceous border by far the most useful and beautiful is *Triteleia laxa*, which, although introduced from California in 1832, appears as yet to be little known, or it certainly would be more cultivated than it now is. The scapes grow from a foot to 18 inches high, and bear umbelliferous Lily-like heads of bloom, resembling in miniature those of the well-known *Agapanthus*, but, instead of being of that colour, they are of a rich Tyrian purple and most valuable for cutting, affording as they do one of the choicest bits it is possible to cull from the open ground at this season. Notwithstanding the length of the scapes, they are of a firm, stiff nature, so as to stand erect without support, and, as their interior construction somewhat resembles that of a reed, they take up water so freely as to last almost as long in it as they do on the plant, which is a great recommendation to any flower used in a cut state. I have not as yet tried them for forcing, but hope to do so this next spring; and, if they will stand artificial heat to get them in by March or April, they will form very attractive objects and show up in favourable contrast with *Spiræa*, *Deutzias*, *Lily of the Valley*, and other light flowers usually so plentiful at that time. The best way to treat them is to plant in a partially shaded situation, in moderately rich loose soil, where the drainage is perfect, otherwise they are apt to rot away during the winter; but where the above-named favourable conditions can be secured they grow readily, and soon become fine strong masses that increase in beauty each year. In planting the bulbs should be buried at least 3 inches deep, and be covered with sharp sand to afford them a dry bed when at rest, and if the surface of the ground is then covered with a handful of cocoa-nut fibre, leaf soil, or some other non-conducting material, they will be all the better for it, and flower much more freely than if taken up annually, and subjected to the drying many half-hardy bulbs undergo. As the foliage is always very spare, the plants should receive every encouragement while growing and blooming, by giving them an occasional soaking with liquid manure and keeping them perfectly free from weeds, or being encroached on by others of a more spreading habit, till they ripen off naturally. *Triteleia uniflora* is also deserving a place in the herbaceous border, however select the occupants of the same may be, as it sends up its flowers in the most profuse manner when once it becomes thoroughly established. The same kind of soil, treatment, &c., required for *T. laxa* will likewise suit this, or any of the others, all of which are desirable, but the one specially under notice is so exceedingly choice and showy that it should be in the hands of all lovers of this class of plants. *J. S.*

Roses in Devonshire.—Fifty of the finest established exhibition Roses in cultivation which do best with us in Devonshire:—

- H.P. Alfred Colomb
- H.P. Amelia Host
- H.P. Antoine Ducher
- H.P. Auguste Rigotard

Strawberry Pioneer.—This superb new Strawberry is a few days earlier than the Black Prince, rather above medium size, flesh firm, colour bright red, and well flavoured. It is the greatest acquisition yet introduced in the way of early Strawberries. E.

Orchids in June.—Not the least recommendation of Orchid culture is that as the summer comes to its height and glass-grown flowers are least desired, the floral products of the houses wane, to come again when the out-of-door attractions are fewer. Nevertheless June has presented the following:—

- Dendrobium amœnum (pretty, tree flowerer, and deliciously fragrant)
- " Dalhousiaium crystallinum
- " Parishii
- " Pierardi latifolium
- " barbatulum
- " fimbriatum oculatum
- " japonicum chrysois
- Cattleya Mossiae
- " Mendeli
- " Leopoldi
- " Forbesii
- " Schilleriana Regnelli
- " intermedia
- Laelia purpurata
- " cinnabarina
- Aeranthus species (a curiosity)
- Angraecum falcatum
- Aerides japonicum retusum
- " affine
- " suavisimum
- " virens Dayii
- " tessellatum
- Saccolabium retusum
- " guttatum
- " ampullaceum
- Cypripedium longifolium
- " Lowii
- " barbatum nigrum superbum
- " oiveum
- " Roezii
- " spectabile
- Vanda suavis
- " tricolor insignis
- " amellata
- Stanhopea Wardii species
- Sobralia macrantha maxima
- " Woolley's variety
- Odoglossum stelligerum
- " Rossii
- " roseum
- " angustatum (spike 9 feet, branching, curling in most eccentric fashion. Many hundreds of flowers, very pretty in the mass, and quite unique in colour. Little known, I believe, but well worth cultivating in the cool house)
- " stellatum (pretty, lasts a long time in flower)
- " Pescatorea
- " cirrhosum
- " cordatum
- " Roezii
- " Lindleyanum
- " vexillarium
- " luteo-purpureum
- Mesospidium sanguineum (bought at Stevens' as O. cirrhosum)
- Mesospidium vulcanicum
- Gongora species
- Acropora Loddigesii
- Bifrenaria aurantiaca
- Angulca Clowesii
- Oncidium auriferum
- " Wentworthianum
- " Papilio
- " pulvocatium (a rich mass of flower, very desirable)
- " flexuosum
- " phymatochilum
- " sociatulum
- " Phelpsianum
- " altissimum
- " triquetrum
- " roseum (a singular flower in form and colour—indeed unique; should be in every collection; in intermediate)
- " pumilum
- " Marshallianum
- " crispum grandiflorum
- " divaricatum
- " concolor
- " barbatum
- " articulatum (small, but very pretty; many flowers)
- Epidendrum vitellinum majus
- " macrochilum
- " species (named by Reich. atropurpureum)
- Disa Henschellii (most disappointing. A very small blue flower, like a pale Campaoula; not worth growing)
- Masdevallia Veitchii
- " Harryana
- " Lindeni
- " caudata
- " nycterina
- " amabilis
- " ignea
- " cocinea
- " ochthodes
- " Peristeria
- Colax jugosus
- Brassia Lawrenceana
- " caudata
- Trichoplia coccinea
- " crispa
- " tortilis
- Phalaenopsis grandiflora
- " aurea
- " amabilis
- " rosea
- " Ludemanniana
- " cornu-cervi
- Brassavola species
- Lycaste aromatica
- " Harrisoniae
- " Deppei
- Maxillaria tenuifolia
- Calanthe Masuca
- Bollea Lalindii

Edward W. Cox, Mount Mount, Mill Hill, June 28.

The Cucumber and Melon Diseases.—I have believed from my first acquaintance with this pest, that all along we have been writing of two diseases, hence I called it the new Cucumber disease. Last year I had neither swelling at the roots nor gumming, this year the Cucumbers have gumped, but neither roots nor stems have swollen; in fact, I have known

the disease called gumming for years, but never saw the pest of last year and this until about a year ago. With all deference to Mr. Smith's theory of worms, I should hold that those found were the product rather than the cause of the disease of which I have written. To all appearance the initiative is fungoidal. A few red spots appear on the leaves, this runs into red rings; and the substance of the leaf corrodes as if eaten out by rust. Peculiar spots and circles have appeared on the fruits; those on the Melons have generally been of a higher colour than those on the Cucumbers, some of the former, in fact, being bright as the red rust on Rose leaves; and not unlike the exaggerated cases frequently found on such, when the affected parts thicken and swell into a raised red excrescence. In such exaggerated cases the fruit quickly decomposes and is utterly destroyed; in fact, the appearance and conduct of those red spots and circles are so totally unlike common gumming in any of its stages that it is hard to believe that they are the same thing, only in different degrees of development. The gumming may be the ultimate product of the ruddy spots and rings, but there is this difficulty to be met and mastered before that theory can be accepted—that I have never seen these symptoms associated with gumming before, and that last year the red marks and blotches did not produce any gumming. This season the disease of last year and gumming succeeded each other in the order here stated on the Cucumbers but not on the Melons. Fortunately I have had no personal experience of this disease till now, but I believe it is a fact that Melons seldom gum, while Cucumbers are subject to it. But this new disease has another distinct peculiarity—gumming reveals or develops itself as an excrescence, but most of our affected Melons had a depression over the whole of the scar. It is difficult to account for these differences if all the symptoms proceeded from one disease. Fortunately for the present, and by the exterminating power or stimulative energy of the Salus, I have now no samples of the red rings or spots to send, though I find a little gum on some of the fruits of the Cucumbers, which comes out suddenly—as a sudden eruption of living organisms might be expected to do, or a surplus of poisoned sap. I have been questioned about the strength of our Salus broth; it was strong. A good thick sprinkle was scattered over the surface at times, and watered on. At others Salus, at the rate of an ounce to a gallon, was stirred up in the water and poured over the roots. The whole of our young crops of Cucumbers and Melons are perfectly clean. The early Melons, badly affected at one time, are now carrying an enormous load of fine fruit—about a hundred in a small house, so that we have reason to be proud of the powers of Salus and grateful to its discoverer. As a proof that Salus does not lower the quality of Melons, it may be added that the flavour is excellent, and that a Reid's Scarlet-flesh treated to very strong doses of Salus broth took the 1st prize from some first-rate green-fleshed Melons exhibited at the horticultural *file* of the Suffolk Agricultural Society at Sudbury on June 28 and 29. D. T. Fish.

Silk Culture in Great Britain.—Permit me, in resuming the brief account of my silkworm education at Colchester, to correct a few statements in your article (p. 756). 1. At the bottom of the first column "Dr. Wallace tells us he has had shoots on 'three' trees, which in one year grew 5 feet to 6 feet long." For "three" read "these," a great number of trees having shoots that length. 2. June 1, the minimum temperature is given at 44°, this being the reading in the cellar; during the day the thermometer was moved into the silkworm-room, and the temperature recorded there afterwards. 3. In the sixth line of third column the words, "not the common fruiting Mulberry," are introduced; this is not my expression, and it is not correct. When silk is required then it is desirable to feed the worms on the White Mulberry; but when grain only is required the Black Mulberry, the common kind, is equally valuable as food. I am, in fact, now using the leaves of the *Morus nigra*. I wish this point to be generally known, that every one who can command the leaves of the Black Mulberry may be aware that they may be used for grain culture. 4. I omitted to state that of the "vers zebres," or black silkworms—the valuable race from Southern Europe—four hatched out on June 5, and fifteen on June 6; two more hatched out on the 13th, making in all 457 worms out of 500 eggs. They have now nearly all moulted or changed their skin for the first time, and are feeding well. On the 13th, finding that even in the cellar, at a temperature of 58°, the young worms began to emerge, I brought up my stock for the year—two cards, containing about 1½ oz. of grain by weight (Brienza race) into the *magnanerie*, and disposed them ready for hatching. On the 14th, 15th, 16th, and 17th nearly all the worms emerged, leaving a few stragglers, which in a large education would be thrown away as *retardaires* and worthless. Since then they have had a change of bed, *défillement*, and are feeding up regularly for the first change. Leaves on the Black Mulberry trees are from 2 to 2½ inches in

diameter, shoots on the White Mulberries are from 6 inches to 1 foot in length, leaves 1 inch to 1½ inch, and on some trees 2½ inches in diameter. My *magnanerie* is a room on the ground-floor, facing south and west, and therefore catching a large amount of sunshine. At the westerly window in the afternoon a large amount of sunshine enters, and this accounts for the temperature rising to a maximum at about 3 P.M. There being no room over it, a considerable amount of calorific enters through the slates of the roof. I am thus enabled to keep up a high temperature without the aid of fire during all sunshiny days. The leaves are given to the young worms at 7 A.M., 11 A.M., 3 P.M., and at 6 P.M., cut up into fine pieces with the aid of scissors. "*Défillement*," or "cleaning," is effected by spreading a net over the tray of worms the first thing in the morning, and scattering over it the cut food. Silkworms always follow their food, attracted by the smell which is exhaled from the cut and juicy edges of the leaf. To do this they crawl through the meshes of the net and leave their old bed. At the next feeding time they must be examined, and if they have risen well, *i.e.*, all together, the new net, worms, and food, may be lifted off, and the old net with the dried food and other *débris* thrown away. There are generally a few weakly worms remaining with the *débris*; these are of no value, and may be thrown away on the rubbish-heap. If the worms have not risen well, which happens sometimes if the temperature is too low, or the old bed too fresh and moist—*i.e.*, if too much food has been given over-night—it will be necessary to feed over the new net a second time with finely cut fresh leaf, to attract the laggards to a fresh repast, and to deter taking off the net till the afternoon. Each day's hatch is kept separate, it being of the utmost importance that each tray of silkworms should go through their change all at the same time. To do this the individuals must all be of exactly the same age, and be kept so throughout the growth. Alex. Wallace, June 18.

Temperature of the Silkworm Room.

June	Minimum.	7 A.M.	9 A.M.	12 noon	3 P.M.	6 P.M.	9 P.M.	Hygrometer.	Wind.	Rain, &c.	Barometer.
12	61	65	66	67	70	70	68	—6½	E.	Heavy at night, with thunder and lightning	29.7°
13	64	64	64	65	66	67	65	—6½	N.E.	Dull morning, sunshine at mid-day.	29.8°
14	60	60	62	64	65	66	65	—6½	N.E., breezy	—	30.0°
15	60	60	61	64	67	66	64	—6½	N.E., fresh	—	30.1°
16	59	60	62	65	67	69	67	—	N.E., fresh	—	30.1°
17	63	63	64	67	69	70	68	—	N.E., breezy	—	30.1°
18	63	64	65	69	70	69	68	—	Slight, E.	—	30.0°
19	64	64	66	69	72	72	70	—	Slight, N.E.	—	30.0°
20	64	64	65	69	71	70	68	—3	N.E., slight	—	30.0°
21	63	64	65	68	70	69	67	—5	N.E., breezy	None in forenoon, slight in night	29.8°
22	64	65	67	69	69	69	67	—5½	Breezy, S.W.	Heavy shower in day	29.4°
23	64	64	65	66	67	66	64	—6	Breezy, S.W.	Slight in day	29.4°
24	58	59	62	67	69	69	67	—5	Slight, N.	—	30.0°
25	60	60	62	67	69	70	68	—4	Slight, N.	—	30.1°

Note.—No fire-heat was used. From the 16th to the 21st my hygrometer was sent away for correction.

"Vers zebres" are now in their third age, dark-coloured, and very handsome. Four feeds are given per diem—at 7 and 11 A.M., 3 P.M., and 6 P.M., of Black Mulberry leaves. The bulk of the silkworms are now in second age, the earliest, hatched out June 12, passed their first moult June 19 to 21, and are nearly ready for the second moult. Those hatched out on the 17th are now just passing out of the first moult. White Mulberry shoots are now 12 to 18 inches long, with leaves 2 to 3 inches in diameter. Black Mulberry leaves measure from 2 to 4 inches in diameter. It may not be generally known that picking the Mulberry leaves with judgment from the black fruiting tree, so as to leave the bud and terminal or last leaf intact, does not injure the fruit, but rather the contrary; the better circulation of air and free admission of sunshine causes the fruit to ripen a fortnight earlier than it otherwise would do, securing it before autumnal rainfall, while the tree in a month's time is again completely covered with foliage. No one who has not seen this done will believe it, but it is nevertheless true. Alex. Wallace, Colchester, June 25.

Identification of Potatoes.—At the International Potato Show, held at the Alexander Palace last

autumn, it will be remembered that, excepting Mr. Porter, all the Scotch exhibitors put up Porter's Excelsior under the name of "Handsworth." As I have not grown the Handsworth for several years I procured seed of a true stock from a market grower who has had it for many years, and now find that it is entirely distinct from Porter's Excelsior; the Handsworth has a shorter top and is slowerless. At the same show a coloured kidney was shown as Crimson Ashleaf: this was thought to be identical with Purple Ashleaf, to which it bore in the tuber a close resemblance. I am glad to find that it is distinct. Princess of Wales, a pretty coloured kidney, also sent from Scotland, is identical with our Trout Kidney. Grampian, a good looking red sort from the North, is quite distinct. *A. D., Bedford.*

Cutting Down Trees.—In the *Gardeners' Chronicle* of June 30 I observed, in an article of Mr. Alexander Forsyth's advocating the cutting away old shy-bearing fruit trees to their base, and encouraging the growth of new branches, &c., he instanced a successful case which I had pointed out to him in my grounds on his going over them heretofore. This having occurred a great many years ago he may well have forgotten the details of the case, which are instructive, and have influenced many operations subsequently. They had no reference to fruit trees, but to an Oak, the specific name of which I forget. This was planted more than forty years ago, and when an ornamental shrub about 7 feet in height, my coachman, after putting his horses in the carriage, left them while going to his room for his coat, during his absence, from some alarm, they rushed out of the stable-yard with the carriage, and broke off my pretty Oak close to the ground. This was carried away, and the earth put in order. In the course of the following year I observed three or four young shoots spring up from the spot on which the Oak had stood, and having selected the strongest I cut away the others. This grew rapidly, and when I called Mr. Forsyth's attention to it, and gave its history, it was probably 8 or 10 feet in height. This must have been more than thirty years ago. This tree is an evergreen Oak of large foliage, and greatly admired. It has grown up with a straight stem, now 7 feet in circumference at 3 feet from the ground, about 60 feet in height, with extended branches covering a space of 40 feet. About fifty years ago I owned a plantation at a distance, chiefly of Larch and Ash, amongst which several common Oaks had been planted. After some twenty years of age they had become stag-headed, and in very unpromising condition, and as soon as I saw the result of my home accident I had all the Oaks I have referred to cut down to their bases, and treated subsequently in the same manner, and they grew away freely with straight upward stems, with every promise of their ultimately becoming fine timber and superior to any Oaks in the neighbourhood. *C. Lawrence, The Querns, Cirencester.*

Coltsfoot.—Your correspondent, "E. W. W.," inquires so earnestly as to the destruction of this weed that I cannot resist offering a few notes upon the subject. Coltsfoot (*Tussilago Farfara*) is remarkable for a large-branched, brittle, and succulent rootstock. This portion of the plant is highly tenacious of life, so that the least bud left in the soil will be certain to grow. No wonder, then, that "E. W. W.," complains that after picking out all the little bits it comes up "as luxuriant as ever;" this, of course, meaning all that could be conveniently got at. But besides this method of increase by division of the rootstock, it should be understood that it is one of the most prolific of seeders, as each head of flowers may perfect from 100 to 200 seeds. The plant flowers before the leaves appear, and the somewhat small yellow stars excite but little attention in early spring, but when the large flat leaves appear the farmer is made sensible of the presence of a noxious weed, and this is just the time that he commences to hoe it up. Now as this is exactly the period at which the seed is ripened, his very bustle either causes much of this to be hoed in on the spot, or it is sent adrift by means of its parachute and so becomes scattered far and wide. Anon, fresh buds spring up from the uncut portions of the rhizome, and hence your correspondent's complaint of the difficulties attendant upon the destruction of Coltsfoot. In some of our stiff marls we had an abundance of this pest which now, I am happy to say, has been so successfully got under that I deem it right to explain our plan of action. The Coltsfoot from its underground growth usually appears in rounded isolated patches, and if these be looked to in time by hoeing before the seeds ripen this fertile source of mischief will be avoided. The leaves will soon after appear, when the hoe should be again brought into use to cut out the buds as deeply as can well be done. By this means the plant will profit but little by its early development of lung. Still the succulent rhizomes will make another effort to get on in life, when a second attack should be made upon the leaves, which, with hand picking at the next ploughing, I have usually found successful. One difficulty, how-

ever, in dealing with this plant will be found in the fact that the labourer is not usually aware of the importance of picking up these succulent morsels; his attention is mostly confined to Couch picking, and he understands but little beyond it. Hence, then, we have found that where the plant had become established in the before mentioned centres it can readily be got out with the fork—a plan which I recommend in such cases. *B.*

Roses Duke of Edinburgh and Lord Clyde.—In the article "English Roses" of your admirable and interesting Rose Supplement, these two Roses are cited as being "sent out" by William Paul & Son, of Waltham, instead of by us—an error we of course hasten to correct. We—Paul & Son, Cheshunt, sent them out respectively in 1868 and 1863. The question of their raising has been already fully discussed (*ad nauseam*) in your columns. When to the list of Roses "sent out" by us are added all Mr. Laxton's, we think we substantiate our enviable distinction of having raised or sent out more good Roses than any other English nurserymen. In our Mr. Paul's remarks on seasonable Roses, one of the new Roses of 1876-77 should be Marquise de Murinais instead of Marquise de Nivernais. *Paul & Son, Cheshunt.*

Subterranean Cucumber.—The Cucumber of which we give a figure (fig. 8) was grown by Mr. Elphick, gr. to E. Frewen, Esq., Brickwall, Horthiam,

FIG. 8.—SUBTERRANEAN CUCUMBER (REDUCED).

Sussex. The colour was a very pale yellow, almost white, which is accounted for by the circumstances under which it grew. Mr. Elphick says that he took it from the root of the plant as it pushed its way aboveground. The peculiarity in question may be accounted for by supposing that a flower had been developed underground, or that it was produced aboveground and grew downwards into the soil for a time, subsequently turning upwards. Several cases of underground fructification are known, as the common earth-nut (*Arachis hypogea*) and some other Leguminous plants. There are also cases in which the flower is formed underground: such flowers are usually closed and self-fertilising. As we did not see the specimen growing, we cannot be sure what is the correct explanation. The seeds were imperfectly formed in the Cucumber in question. Has any one seen or recorded a subterranean Cucumber? *EDS.*

Floral Decorations: Amateur and Open Classes.—Your remarks in a late issue upon the exclusiveness of the West Kent Horticultural Society and the opposite course of the Royal Botanic Society, are deserving of consideration by the framers of schedules of several other societies. For their information it should be recorded as one of the results that the number of exhibitors of table decorations at the show of the former Society last Saturday was much smaller than usual, while the number at Regent's Park last Wednesday was greater than it had ever been. But this is not all; a more important fact remains to be mentioned—what you prophesied proved true;

amateurs took almost all the 1st prizes. Ladies need no longer be under any apprehension of competing with gardeners or with florists, for a few flowers tastefully arranged with a proportionate quantity of foliage must always be preferred by competent judges to those massive groupings in which the arranger strives, by the quantity of flowers used, to dazzle the beholder and to hide his deficiency in art-qualifications. It is not necessary to strip a greenhouse, or to spend a bank-note at Covent Garden, in order to furnish a dinner-table with floral decorations, artistically arranged. The 1st prize at Regent's Park for a dinner-table completely furnished, and also the 1st prize for a dinner-table florally decorated, were both taken by a lady who used less materials than any other exhibitor there; but then everything that she put on "told," by which I mean that you could not well have added or taken away anything without interfering with the effect. I do not at all mean to imply that amateurs are all capable of doing this sort of thing, but nevertheless it is what all amateurs should aim at, and practise until they can do it. Again, the leading prizes at the West Kent show (which, by the way, is one of the best, if not the best of all the suburban shows, and is always numerously attended) were taken by ladies who used comparatively very few materials, and if any of them happened to be at the Botanic *fière*, and saw the want of lightness in arrangement which characterised the tables of most of the gardeners and florists who exhibited there, they must feel sure that their own natural and unconventional groupings need not fear comparison with the productions of those whose larger experience and greater opportunities of getting flowers places them in a more favourable position, but whose want of elegant taste so often prevents their being able to turn their advantages to account. The charming softness of the colour arrangements produced by the Misses Scott with wild flowers only, and the refreshing coolness of the foliage with which Miss J. S. Lovibond's table was almost entirely decorated, were the subject of general admiration. It is only just to florists and professional decorators that I should add my conviction that the public are far more to blame for what I object to than the trade. I have heard several complain that they dare not supply decorations as they would like, and that they are obliged to send in what they know is wished for. In fact, the public want a large quantity without much regard to quality; they pay readily for raw material, but they will not pay for art, or rather they look upon it as only an excuse for supplying fewer flowers. No one who has attended displays of floral decorations such as those at Bickley and the Botanic Gardens can have failed to notice the marked improvement that has taken place in the art of arranging flowers during the last few years; but unless I much mistake, the improvement will continue for some time to come: assuredly there is room for it in many details, and it will come from amateurs. *W. T. T.*

Two Days' Rose Shows.—The Aquarium Company is the only public body that has this season attempted this, and it is to be hoped that all members of the National Rose Society will remember that they are pledged to discountenance them. *V. W.*

Téosinta (Reana, or Euchlæna luxurians).—The experiments as to the culture of this plant which I made in 1876 seem to me to be decisive, and to leave no doubt as to the impossibility of using it as really useful forage in France. I have raised more than one hundred plants of it, placed in all aspects except the north, some being watered, the others left without water. The young plants were planted in April, and were checked a little by the coldness of the spring, but made up for lost time during the first few days of May. The plants that were situated in rich soil and watered rose to the height of 2.50 m., or a little more, some even to 3 m., forming large and vigorous clusters of ten to twenty stems, leafy and very tempting as forage; those which had been left without water, and which had suffered from the dryness of the summer, did not exceed 1 m. in height, and the stems formed scarcely any branches. Until the end of October I despaired of seeing these plants in bloom, but on November 7 two terminal male panicles began to unfold. Others followed, and soon nearly all the plants had developed their male panicles, which are exactly like those of Maize. At the same time the female flowers, consisting of small axillary panicles, on the side branches of the main stem, pushed out their long, reddish-purple stigmas, and they would no doubt have been fertilised if there had been any pollen, but not a single stamen had unfolded itself. The nights also were too cold to allow of the ripening of the pollen. At the time when the male panicles began to show themselves all the leaves dropped off and left long stalks entirely stripped. The plant is very sensitive to cold. On the night of November 9 or 10 the thermometer suddenly fell to zero, and that was sufficient to kill the panicles and the leaves of those plants which were without shelter. The lowest temperature of the year 1876 at Collioure

was 14.7 (58.5 Fahr.), and the entire amount of heat which my plants received from April 30 to November 30 was 4033° (7259° Fahr.). This is nearly double the quantity needed by Wheat to grow and ripen its seed, and much more than is required by the latest species of Maize, not excepting even Mais Caragua. The resemblance between Reana and Maize is otherwise very great, as is proved by the fact that two of my plants were attacked by *Ustilago maydis*, which has the same effect on them as on Maize. I consider that in order to bring about the complete fertilisation of Reana luxurians at least 6000° of heat are required, that is to say, the same quantity needed by the Date Palm in order nearly to ripen its fruits. It is only as mild as this in the extreme south of Spain, Sicily, and other similar localities, where the perfect cultivation of Reana may be hoped for, and it would still require copious irrigation. Under the same circumstances Maize would render twice or three times the quantity of forage. But if Reana cannot be utilised in Europe it could probably be used very profitably in the hot and damp tropical countries, as in some parts of Mexico, Guatemala, the Antilles, New Caledonia, India, &c. I think it would make a good forage plant in these countries, possibly too the seed could be used as food by men, or at least for domestic animals. This would be an experiment worth trying. *C. Naudin, Collioure, France.*

Pear-leaf Fungus.—Can you inform me the name of the fungus or lichen affecting the enclosed Pear tree leaves? About two or three years ago I observed it on one tree, but as it did not spread or appear to affect the vigour of the tree I took no further notice of it, but this year it has spread over all the Pear trees (and not on other trees) in my garden, upwards of 100, and has caused them to cast their fruit. I don't know what course to pursue to destroy it, except perhaps a strong dressing and a large admixture of sulphur in the autumn after the trees have been pruned. Any information or advice will be thankfully received. The spores appear to have been driven by the wind, as most of the trees are to the south of the one first affected, and the wind till lately has been long in the north and north-east. The Pear trees are all grown on the pyramid and bush system. *George Wood, Solicitor, Rochford.* [The fungus is *Ræstelia cancellata*, by no means common, but at times it is very prolific and virulent. *EDS.*]

Salus, Cucumbers, Melons and Carrots.—Our Melons, spite of green-fly, seem to prosper. Last year we had not a single one. Our Cucumbers are also a decided improvement, but Salus has won my gardener's heart for its effect on a bed of Carrots: the appearance of which confirm his raptures. *E., Melksham.*

Notices of Books.

Contributions to Mycologia Britannica. ("The Mycomycetes of Great Britain, arranged according to the Method of Rostafinski.") Translated from the Polish by M. C. Cooke. 8vo. Williams & Norgate. Pp. 96 and iv., pl. lith. 24.

It is a serious grievance when valuable works on natural history are published in a little-known language, as Polish, Hungarian, &c. The work must either remain a sealed book, especially when the specific characters are given in Latin; or, as we speak from experience, we must sit down to obtain such a smattering of an exceedingly difficult language as may enable us at least to puzzle out the descriptions of the figures. Dr. Cooke, however, in his zeal for illustrating the mycology of this country, has done more than this—has placed himself under a Polish tutor, and has thus been enabled to offer to the public a very useful, and indeed, to the mycologist, indispensable treatise. This assuredly was the more needful, as it seemed impossible to procure the original treatise, a single copy, for a time at least, transmitted to us by Rostafinski, being certainly the only one in England. As the work itself is voluminous, Dr. Cooke has very prudently confined himself to that portion of the work which relates to British species, adding from a supplementary publication those species which Rostafinski had an opportunity of studying in England. All the first twelve plates have been reproduced, the only one omitted being a photograph of inferior interest; so that, as far as British mycology goes, the treatise may be considered complete. As the expense of preparing so many figures, in addition to other matters, has been considerable, we sincerely hope that the sale may be such as to indemnify him for the outlay, for no one in this country expects to derive any emolument from works of any branch of natural history which has only

a limited number of followers. We cannot give sufficient credit to the translator for the disinterested manner in which he follows out his favourite study, and we feel quite sure that a sense of gratitude for the constant aid which is given to mycological research by his handbook will induce its numerous readers to give (for their own certain advantage) a helping hand in the present instance. *M. F. E.*

THE VINE IN THE GREENHOUSE.—This might be termed the vinery, but then a vinery is supposed to be a house devoted entirely to the culture of Grapes, whereas a Vine may be grown in a greenhouse with plants below it on the stage, though in this case it is best to have plants that flower before the Vine overhead gets too dense in growth, and which can be stood out-of-doors during the summer, or which, if they cannot be stood out-of-doors, can be placed in a cold frame. But if there be plenty of side light to the greenhouse plants may be satisfactorily grown, as the leafy canopy overhead yields grateful shade; and if the plants get drawn a little, why, there is no great cause for alarm.

At this season of the year, when the days are longest, and warm June has given place to hot July, the Villa gardener's Vine requires considerable attention. As a matter of course, we are referring to a Vine to which no fire-heat has been applied to hasten its growth. Several matters require attention, and one of these is that of stopping the shoots. The fruit being produced upon young shoots of the present season's growth, which started from the mature buds on the young wood of the previous season, it is usual to stop all these young shoots, except the terminal or leading one in a young Vine, at one eye or point beyond the fruit; and where the spur system is practised to stop those shoots which may not show fruit at a similar length, as if allowed to grow longer their shade would injuriously affect the others. This is the general practice of Vine cultivators, and if it is not exactly comprehended by the uninitiated it yet is soon understood when reduced to practice.

In the case of weak Vines—Vines that it is desirable to get into as strong a growth as possible—it is advisable to allow the shoots to grow a few joints further if the extent of the roof will admit of this being done; and for this reason—in order to promote a more vigorous root-action. Vegetable physiologists assert that there is a correspondence between the roots and the branches of a plant, and that the one acts to induce the other to vigorous effort when both are correct in action. Hence it is advisable, in cases, not to cut off part of a shoot, but in due time merely to nip out its terminal bud, as then less of a check will be given to the system. When the shoot thus nipped is found too long for the space, it may be gradually shortened, when the first-formed leaves have so increased in size, or the laterals left are so numerous that the reciprocal action between the roots and the top may be maintained without any great check to the system, though a joint or two at the end of the shoot may be removed. In very vigorous Vines, where, from the size of their leaves, much more space is requisite for their full exposure to light, the bearing shoots may be stopped an inch or so beyond the bunch, taking care, however, to give full exposure, and thus complete justice to the leaf situated close to the bunch, as then it will be sufficient to maintain a requisite flow of nutriment to it.

When it is desirable to strengthen the base end of a young Vine the terminal bud may be nipped out with advantage when the shoot is from 3 to 6 feet in length. In thus removing the terminal bud of a young shoot, to increase its strength at its base, some of the buds near the point will start into growth, and of these the strongest must be selected as leader.

We have put these directions in as simple a form as possible, but if they appear a little difficult at first sight the reader will soon come to understand their application when he has had a season's experience, or, better still, a lesson from a capable gardener.

In a vinery where the house is solely devoted to the growing of Grapes, what is known as the "long-

rod system" is that generally employed in cultivation; but for an ordinary greenhouse what is known as the "spur system" is invariably followed, and it is known as the "spur system" because all the shoots produced and retained during summer upon established Vines, and all, with the exception of the leading shoot in young Vines, are cut down in winter to one or more buds. The "spur system" is best for the greenhouse, because it involves least shade. Lateral shoots should be encouraged, but chiefly at the base of young bearing shoots; those nearest the end next the fruit being first removed, and then in autumn, when there is no danger of starting into growth, the smaller-looking buds at the base—those from the point downwards—may be picked out, leaving the leaves untouched, and thus a greater portion of substance will be lodged in the buds and wood ultimately left than otherwise would have fallen to their share. Under such treatment winter pruning may be effected shortly after cutting the fruit, or as soon as the leaves turn yellow, if it be deemed necessary to do so.

The matter of thinning the fruit also needs attention. This should be done as early as convenient, when the berries have attained the size of half-grown green Peas. The fact is, that the sooner the redundant berries are cut out the better will it be for those that are left behind. As a matter of course the thinning should be regulated by the average size that the berries of the respective varieties arrive at—a knowledge gained by experience. In the case of a greenhouse where plants are grown in company with the Vines it is best to thin out more than would be needed in a vinery, and for this reason, that if left thick and firm on the bunch the berries are sometimes apt to become destroyed in part, if not wholly, by the mould and damp in the autumn. Therefore, the bunches should be loosely hung with berries, and that because at the time when they need to be kept as dry as possible the air may circulate freely through them. In thinning it is a good rule to cut out the centre berries, *i.e.*, those that are inside instead of on the exterior of the bunch, and to do this properly, and at the least danger of damage, a pair of sharp-pointed Grape scissors should be used. Some who engage in this delicate work steady and hold the bunch in position by means of a hooked stick, and so avoid the necessity for holding it by the hand. The task of thinning should be done in the mornings and evenings when the weather is cool, and not during the day when the sun shines fully on the house.

Reports of Societies.

The West of England Rose Show: Hereford, July 6.—When her majesty the Rose issues cards for her reception all Herefordshire seems to indulge in temporary insanity, for nowhere have I met courtiers more enthusiastic and devoted to their Queen than are the inhabitants of the old red sandstone. A beehive is a joke to the Shire Hall as it appeared this morning; the earnest excitement of the ladies who are decorating in the corridors, while the gentlemen are staging their own Roses with their shirt sleeves tucked up, being of itself sufficient to cause wonder and admiration when we look back at what a Rose show was, even ten years ago. "Small," but not so "early" as usual, this gathering of July 6, 1877, will be memorable for the rare quality and colour of the Roses shown.

Judging from the form of the leading exhibitors one would think it was the day of the season for cutting. A sad mistake was made (and this must not occur again) in fixing the same day for Hereford and Oxford. Hereford sadly missed Messrs. Paul & Turner, (who were at Oxford), for their own sakes as well as of their Roses, for these annual *réunions* of Rose-growers have a social charm, and are the origin of many pleasant friendships. The disappointment expressed was genuine on hearing that Mr. Camm had missed his last train, treasures and all.

But to the room. Oh, that we could devise some mode of breaking up the everlasting monotony of the ribbon border of four long rows of flowers all alike into groups, into classes—anyhow, so as to introduce shrubs, Ferns, and Palms. And why not make use of the orchestra, as at St. James' Hall on Tuesday last, for one or two *specialties*, and to obtain a *coup d'œil* worth traversing England for.

Were I to enter into detail I should find myself on ground thoroughly exhausted by the *Gardeners' Chronicle* of last week. I will, therefore, say generally that the quality of the leading exhibitors, nurserymen, and amateurs was tip-top, and that there were without doubt a larger proportion of faultless blooms here than at St. James' Hall, or any other collection I have seen this year. One could not

suppress a sigh at meeting a few old friends, e.g., Baroness Rothschild, La France, Captain Christy, Mons. Noman, and a few others of delicate petal, looking as if they had passed a restless night; as, in fact, they had, for Herefordshire was visited yesterday with a deluge of rain (and some hail), lasting for many hours. In novelties I noticed among Mr. Cranston's twelve Henry Bennett, Abel Carrière, and La Rosière, all very dark; and Madame Prosper Langier, a bright and distinct carmine. Mr. Noble showed a brilliant box of Queen of Bedders. She answers to her name, and will catch the eye anywhere, but is not a show Rose. To all of these "a rividerla!"

Mr. Cranston, invincible at home and dangerous everywhere, was, we thought, very strong; but he says that the season being so late he is not even yet ready. Mr. Cant richly deserves his honours. Mr. Baker, of Heavitree, brought a Rose show by himself, and won the challenge cup given by Mr. Cranston with forty-eight blooms, grand and superbly staged. This cup was awarded to Mr. Jowitt last year, and will become the property of whichever of these two wins it in 1878, unless a third candidate steps in, like the empire in the tale of the oyster, and swallows it for at least one more year. But the best Devon and the best Hereford are hard to beat in Roses, as at the Royal Agricultural Society of England. But we must not omit to mention a magnificent box of twenty-four François Michelin, ably backed by Marie Baumann and La France. "François" is undoubtedly the Rose which is best shown to-day, no good collection being without him in undeniable form. Mr. Jowitt's box of twelve of the same Rose was splendid, eclipsed only by Mr. Arkwright's *Maréchal Niels*, which were even grander and more level than he had them at the National.

Amateurs in the classes limited to the county have made marvellous advance, and are constantly, as their progress becomes sufficiently marked, promoting themselves into the realms above of the open classes.

It is high time that the practice which obtains still in some quarters of tying up additional foliage should once for all be abandoned. It is against the rules, and is, though perhaps (as Martin Tupper would say) conventional, still a deceit. Moreover, though points are not actually given for foliage, yet, between two very even exhibits, the best foliage and staging would as certainly win the fight as the discovery of any addition to the "truss" would lose it. Such an addition may escape the judge's eye in his tour of inspection, the more so that now-a-days he is not on the look-out for it: the possibility ought not to exist.

But most of all have the "cottagers" distinguished themselves, and I should like to see their Roses staged among the others, instead of being consigned to a side room insufficiently advertised by the customary dexter digit, for they will stand comparison. The knowledge of how to grow, and how not to grow a Rose, must apply to other produce of the garden (universal in this county, but ill-managed and neglected), and ought to be encouraged to spread as fast as Twitch-grass. Now to the floral decorations. It must be a pleasant task for the judge (and I think Mr. Boscawen seemed to like it) to linger alone in a cool atmosphere of grace and poetry for a space of at least an hour, a pleasure enhanced by the hope that presently he will be introduced to the owners of those fair fingers whose delicate tracery he has been ruthlessly criticising. For I note that the moment the door is open he is blockaded by the fair decorators, who want to know why this was wrong, why that was right, and to cull hints for future campaigns. Faces are tell-tales. I saw the triumphant "I told you so!" the remorseful "Oh, why did I leave that so?" and the flash of "Never say beaten. Wait till 1878 and see." The usual weaknesses are still to be found among the contributions—the too evident want of eye for colour arrangement by contrast—pink, orange, red, recklessly crowded together without any neutral gradient to carry the eye from one to the other—the severe ring, as if Roses had been applied with the mathematical precision of the calliper compass—the covering of a surface as if decoration was a performance instead of a graceful adjunct—and the carelessness in finish.

Decorators must not forget that Nature never puts dissonant colours side by side, unrelieved—as in a landscape painting, a colour once introduced must be repeated—Flora does not possess a box of trigonometrical instruments. Finish is a *sine quâ non*—a vase must bear inspection all round—and, as a "pp" in music, so simplicity in the art of decoration must never approach insignificance. Finally, neither Mr. Boscawen, nor any other judge must be treated as infallible in any crotchet! "*medio tutissima ibis*" and "*mens conscia recti*" will win the day. May I ask whether, in Herefordshire, the drawing-room tables are always covered with a white cloth? I should have thought that a maroon or olive-green covering would have given a kinder relief to the eyes of the ladies while at work, and am sure that it would have pleased the audience afterwards. One novelty is worth a record. There appeared in the centre of a dinner-

table a gigantic obelisk of ice; it was suggestive, for one could not help peering into its crystal recesses, if perhaps a fish or newt or any other aquatic reptile might be immured therein, like the spider in a block of pure amber. (Happy thought for next year, catch a fish.) The hostess must weigh well whether it would be expedient to establish such a coldness between at least four of her party of twelve guests, for radiating from a central position it might be infectious. Perhaps it was a memorial of the Arctic Expedition!

I do not hesitate to say that much of what I saw was in extremely good taste, and that the honest rivalry of eight years, even if it has not improved the best of the artificers, has still imparted an influence to hundreds of others which must be rewarded, and has benefited public taste by raising the acknowledged standard of contributors. There is no sign of decay in this now ancient Society of the Hereford and West of England Rose Show. Planted by the best growers, nurserymen, and amateurs, and petted by such talent and beauty as fitted in the corridors of the Shire Hall to-day, I prophesy that new fibre is striking out in every direction. (From a Correspondent.)

Rochester and Chatham Horticultural: June 26.—This is a new Society, formed for the purpose of uniting the practical horticulturists of the three towns which are set down on the banks of the Medway—Rochester, Chatham, and Strood—and for holding an annual exhibition of horticultural produce. The county of Kent has some remarkably good exhibitions, such as Tunbridge Wells, Maidstone, Chislehurst, Sevenoaks, Westerham, Tonbridge, &c., and it is to all appearance so favourably endowed by Nature for the purpose of growing fruits, flowers, and vegetables, that good produce might be looked for in any part of it. Rochester and its suburbs is scarcely a plant-growing district, but it is hoped by the establishment of this annual exhibition that inducements will be held out to persons to grow plants for the exhibition table. The Society has been duly organised, and a good subscription list obtained. The exhibition took place in what is known as The Vines, a part of the green near the Cathedral precincts, and supposed to have been at one time the site of a vineyard.

The leading point of interest was the competition for the handsome silver cup given by the members of Parliament for the city, for the best groups of plants. The possession of this trophy was eagerly sought for by several citizens, but it eventually fell to the lot of Mr. H. G. Regnart, Groveville Cottage, Birstal Road, Rochester, who had large examples of *Pteroma elegans*, extra fine, *Rondeletia speciosa major*, *Plumbago capensis*, *Trachelospermum jasminoides*, *Allamanda Schottii*, *Croton pictus*, *Cyathæa excelsa*, *Echites rubro-venosa*, *Fuchsias*, &c. From Mr. W. Dewsbury, gr. to the Earl of Darnley, Cobham Hall, Gravesend, came well-grown plants, made up mainly of *Crotons* and *Caladiums*, a fine *Maranta zebra*, *Anthurium Scherzerianum*, *Alcoccia Jenningsii*, &c. After these fine plants there was a considerable falling off, the chief honours resting with Mr. Phillips, gr. to Captain Jackson, Meopham, who had capital *Achimenes*, really first-rate variegated *Zonal Pelargoniums*, gold and bronze, and double and single varieties of the *Zonal* section. Of the double varieties *Alice Crousse*, *Asa Gray*, *Crown Prince*, *Aline Sisley*, and *Jewel* were particularly noticeable. In addition to the exhibitions already named the leading ones were Mr. Harper, gr. to W. Lee, Esq., Holburgh; Mr. Daniels, gr. to C. Dickens, Esq., Gad's Hill; R. L. Cobb, Esq., Mockbeggar; and of nurserymen, Messrs. Regnart and Laurence.

The best table decoration came from Mr. Charles Dickens, and some remarkably good cut Roses came from Mr. Harden, gr. to J. Wakeley, Esq., and the same exhibitor was 1st with six blooms also.

In the fruit classes a remarkably good collection of eight dishes was staged by Mr. Dewhurst, which included Black Hamburgh and Foster's Seedling Grapes, Royal George Peaches, *Violette Hâtive* Nectarines, Sir C. Napier Strawberries, and Read's scarlet-flesh Melon. In the classes for black and white Grapes, Mr. Dewhurst was 1st with capital Black Hamburgh and Foster's Seedling, Mr. Phillips being 2d with Black Hamburgh, and R. L. Cobb, Esq., with Buckland Sweetwater.

In the classes for vegetables, an admirable collection of eight varieties, to which the 1st prize was awarded, came from Mr. Phillips, consisting of *Defiance* and *Green Gate* Tomatoes, *Tender* and *True* Cucumber, *Myatt's Kidney* Potatoes, *Ringleader* Peas, and *Short-horn* Carrot; Mr. Dewsbury came in 2d. The best brace of Cucumbers, *Tender* and *True*, came from Mr. Phillips, and Mr. Dewsbury was only just below him with *Cox's* Volunteer. In the vegetable classes all the products were of a meritorious character.

There were some classes for cottagers, but few were found competing. Probably the show was to many of them quite a novelty; and by next year, if another exhibition is held, they will become more familiar with the idea, and a larger quantity of their productions will be forthcoming. (From a Correspondent.)

Brighton and Sussex Horticultural: June 27 and 28.—This Society held its annual summer show on the above days, as usual, in the Pavilion and adjacent grounds. Plants as a rule are seldom seen to such advantage in rooms as under canvas on green turf, but so far as a building is capable the Pavilion possesses many advantages, not the least of which is the pleasant grounds attached, which, although limited in extent, afford an agreeable promenade for visitors, neither is the heat so oppressive as it often is in tents during summer. The opening day was fine, the company numerous and fashionable. The principal collections of flowering plants were arranged in a roomy tent on the lawn; the Ferns, fine-foliage plants, cut flowers, and fruit occupied the spacious rooms overlooking it. In some of the leading classes the exhibitors were not very numerous, but to compensate for this there was all but a total absence of inferior productions. For the Ashbury Cup, offered for twelve stove and greenhouse plants, there were two entries. Balchin & Nell were easily 1st, with a remarkably fine group, in which *Erica Paxtoni*, *E. ampullacea Barnesii*, *Bougainvillea glabra*, *Ixora amboinensis*, *Clerodendron fallax*, *Allamanda Hendersoni*, *Stephanotis floribunda*, *Statice imbricata*, and *Kalosanthes miniata* were both large and well flowered. Mr. E. Meachin, gr. to C. Armstrong, Esq., Withdeane, was 2d, his collection containing a very good plant of *Aerides Fieldingii* bearing four good spikes, *A. odoratum*, *Erica jasminiflora*, *Allamanda Hendersoni* and *Clerodendron Balfourianum*, fresh, clean, and finely bloomed.

Four stove and greenhouse plants.—1st, Mr. Ver-rall, gr. to F. Shentone, Esq., Barecombe.

Eight Orchids.—1st Mr. Rutland, gr. to the Duke of Richmond, Goodwood, who was the only exhibitor, showing an effective collection in which *Aerides crispum*, *A. Lobbii*, *Odontoglossum Alexandræ*, and *Cypripedium barbatum*, were well bloomed.

Four Orchids.—Here again Mr. Rutland was 1st. In his exhibit *Vanda suavis* and *V. tricolor* were not only excellently flowered, but furnished with good healthy foliage down to the bottom—a condition these plants are not always seen in. Mr. C. Driver, gr. to Miss Brodie, Eastbourne, was 2d, showing amongst others a beautifully-bloomed *Lælia purpurata*.

Ten fine-foliage plants.—Messrs. Balchin & Nell were well to the fore, staging an exceptionally good lot, noticeable amongst which were *Croton majesticus*, large, profusely furnished, and finely-coloured; the old but still beautiful *C. angustifolius* in splendid garb; *Stevensonia grandifolia*, *Pandanus Veitchii*, *Areca sapida*, and *Cycas revoluta*, were likewise large and well grown. Mr. W. Miles, Cliftonville, was 2d, showing smaller but very nicely-grown examples, including a good specimen of *Areca Verschaffeltii*, *Cycas revoluta* and *Theophrasta imperialis*. Mr. Driver was a close 3d. In this group was an unusually fine *Alcoccia gigantea* and *Anthurium crystallinum*.

Four fine-foliage plants.—Mr. Meachin 1st, with nice but not over-large plants; Mr. Driver 2d. In his lot *Acalypha tricolor* was very well coloured.

Ferns were also a remarkable feature in the show. Messrs. Balchin & Nell were here again 1st with plants both large and in faultless condition; of Tree Ferns they had *Cibotium regale*, *Cyathæa medullaris* and *Alsophila excelsa* on short stems, but with fine spreading heads; *Davallia Mooreana*, *Gymnogramma corysophylla*, and *Adiantum concinnum latum*, were equally well done. 2d, Mr. Driver; 3d, Mr. Ley, Royal Nurseries, Croydon.

Single stove plant.—1st, Messrs. Balchin & Nell, with an *Anthurium Scherzerianum*, bearing some fifty flowers, but only a moderate variety, the blooms being inferior in size to many of the fine forms of this deservedly popular subject. 2d, Mr. Rutland, with a smaller plant, producing larger flowers; 3d, Mr. Driver, also exhibiting an *Anthurium*.

Eight *Pelargoniums*.—Mr. Meachin 1st, with a finely flowered group; he likewise took 1st honours for four fanics.

Six Fancy *Pelargoniums*.—Messrs. Balchin & Nell again occupied the 1st place, as also for six *Zonals*; Mr. W. Miles, West Brighton Nursery, 2d; Mr. Meachin, 3d. The plants collectively in this class were nicely flowered, but moderate in size.

Cut flowers.—Roses, for the season, were well represented. Messrs. Mitchell & Son, Pitdown Nursery, Uckfield, took 1st in the open class of forty-eight (trebles), with a really good lot of flowers, conspicuous amongst which were *Baron Haussmann*, *Marguerite de St. Amand*, *Adam*, *Edward Morren*, *Perfection de Lyon*, and *Baroness Rothschild*. Mrs. Woollard, The Nursery, Crooksbriidge, 2d. Twenty-four (trebles): Mr. J. W. Piper, nurseryman, Uckfield, 1st; the Rev. R. C. Halls 2d. Twelve (trebles): 1st, Mr. J. Ridout, gr. to T. B. Heywood, Reigate, staging a good stand, the best of which were *Marie Baumann*, *Edward Morren*, *La France*, and *Abel Grand*, large and fine; Mr. W. Martin, Blackstone, Woodman-cote, 2d; and the Rev. R. C. Halls, 3d. Twelve single blooms: 1st, Mr. H. Davis, Horsham, with a

dozen very fine flowers. In the amateur's class for twenty-four Mr. W. Martin was placed 1st, with a good even stand; Mr. T. Gravely 2d; Mr. Davis, Horsham, 3d. Twelve (amateurs) 2d; Mr. Rutland 1st. His Maréchal Niel and Marie Van Houve were grand flowers. 2d, Mr. Martin; 3d, the Rev. R. C. Halls.

Twelve Teas or Noisettes.—1st, Messrs. Mitchell; here Madame Willermoz and Devoniensis were in unusually fine condition. 2d, Mrs. Woollard.

Twenty-four varieties of cut flowers.—Messrs. Balchin & Nell had a fine group, which was deservedly awarded the 1st prize; they were very tastefully arranged, the bunches out too closely packed, so as to give them the dumpy appearance cut flowers too often have when shown in this way. 2d, Mr. Morse, The Nurseries, Epsom.

Fruit was forthcoming in moderate quantities, and generally good.

One Pine.—1st, Mr. Rutland; 2d, Mr. Barnes, gr. to Sir S. M. Wilson, Uckfield. Three bunches black Grapes.—Mr. Vickering, gr. to W. Lee Ewart, Esq., Chichester, 1st, showing good bunches with large hammered berries a little short in colour; Mr. Warren, gr. to J. A. Haukey, Esq., Balcombe Place, 2d. Three bunches white Grapes.—Mr. Warren 1st, with very fine examples of Chasselas Musqué, good in berry and bunch for the kind, and quite free from cracking; 2d, Mr. Aplin, Broadwater, showing Duke of Buccleuch. Eight Peaches.—1st, Mr. Holman, gr. to A. Wright, Esq., St. John's Common, having a really fine dish of Grosse Mignonne; Mr. Rutland 2d, with Violette Hâtive. Eight Nectarines.—1st, Messrs. Balchin & Nell, showing a beautifully coloured dish of Elurge; Mr. Rutland 2d. Mr. Rutland was 1st with James Veitch Strawberries, large and finely coloured. In the competition restricted to the county of Sussex Mr. Vickering was 1st for two bunches of black Grapes. Two bunches of white Grapes: 1st, Mr. Aplin. Mr. Rutland was 1st in the classes for one Pine, six Peaches, six Nectarines, four dishes of Strawberries, and a single dish.

The arrangements of the show were, as they have long been, carried out by the veteran Mr. Spary, whose taste and abilities in these matters are such as to enable him to put everything in the right place to produce the best results. (From a Correspondent.)

Brentwood Horticultural: June 28.—This Society held its summer show in the grounds of W. A. Ogg, Esq., Warley, and it proved to be exceedingly effective and well arranged, and, as far as the products went, was a good one in all respects, excepting in vegetables. These latter, as indeed seems to be too generally the case this season, were very limited in quantity and wanting in quality. In the first class, for specimen stove and greenhouse plants in bloom, Messrs. Bones and Lane competed well, the silver cup offered being awarded to D. McIntosh, Esq., Havering Park (Mr. Bones, gr.), who had in his collection splendid specimens of Anthurium Scherzerianum, Erica obtusa, and E. Paxtoni, the latter being a very meritorious specimen.

For four similar plants O. E. Coope, Esq. (Mr. Bradley, gr.), received the higher award. Ferns (stove) were well shown, C. P. Matthews, Esq. (Mr. Woodhams, gr.), being 1st, with well grown dissimilar varieties—W. A. Ogg, Esq. (Mr. Wise, gr.), having received a well merited equal 1st prize for six splendid plants of *Todea superba*. Pelargoniums were very plentifully shown—the six show varieties staged by Major-General Fitch (Mr. Lane, gr.), were awarded 1st prize, being very robust and well grown; amongst this generally good lot Excellent and Diana were especially so. In the class for six Fancy Pelargoniums D. McIntosh was 1st with well-sustained masses of bloom, Liberty and Princess Teck being perhaps the best. The Gloxinias shown in competition by W. A. Ogg, Esq., and which deservedly received the premier prize, were immense, both as regards size of the blooms and foliage. Roses in the cut bloom division formed along with herbaceous plants no mean display. Mr. Cant, Colchester, was 1st with seventy-two varieties; Mr. Meadmore, Romford, being a neat 2d. Perhaps the most perfect blooms staged were Beauty of Waltham, Comtesse d'Oxford, and Marie Finger. For forty-eight roses, the Rev. Canon Farver (J. Edwards, gr.), Stisted Rectory, was a good 1st. With herbaceous cut blooms Messrs. Saltmarsh carried away the higher award. Dinner-table decorations, &c., were less numerous than has been customary. In the class for lady amateurs, Miss F. Pemberton, Round House, Havering, had a very chaste display, rightly receiving 1st prize; Mr. Burley, Brentwood, sustaining his old fame well in the kindred class, also claimed 1st prize.

Fruits were fairly well shown—the best collection coming from the Right Hon. Lord Petre (Mr. Gadd, gr.), and the best black Grapes from Mr. Farrance, Chadwell Heath—Mr. Woodhams staging splendid bunches somewhat deficient in colour. Mr. Wm. Paul sent a splendid collection of cut Roses, not for competition; and a grand Nepenthes, growing in a square latticed wooden basket, which was labelled *Nepenthes Rafflesiana*—but

which, if our memory is to be relied on, must be a more recent and better variety. Too much cannot be said in favour of the arrangements generally existing at these shows, so thoroughly do all interest themselves in working out the details. The tents were pitched in a continuous semicircle upon the higher ground, others with implements, &c., were placed so as to complete an ellipse, within which area the excellent band was platformed. The liberal owner of the grounds had brought, we believe from Erin, three bagpipe players, which proved a singular additional attraction to the large company assembled. *W. E.*

Richmond Horticultural: June 28.—The annual exhibition was held as heretofore in the Old Deer Park, Richmond. The Society has only been established some three years, yet its displays as regards both the quantity and quality of the various productions are quite equal to any that are to be seen within a similar distance of London. The site where the show is held is most beautiful, and contributes not a little in bringing visitors from the surrounding districts. The principal attractions of the show here are always the groups of plants either in or out of flower, arranged for effect in a space not exceeding 100 square feet. In this there was a numerous and keen competition, the first and second prize lots being both interesting and effectively arranged; Mr. W. Bowell, gr. to Sir H. W. Parker, Richmond, took 1st: Mr. F. R. Kinghorn, Richmond, 2d. The position of these competitors would have been reversed had not the second group been a little wanting in tall foliage, to set off the flowering plants to better advantage. Messrs. Jackson & Son, Kingston, 3d; Messrs. Hooper & Co., Twickenham, 4th.

Nine fine-foliage plants.—Mr. Kinghorn 1st; Mr. Bates, gr. to W. H. Punchard, Esq., Twickenham, 2d—both lots consisting of well-grown plants.

Nine stove and greenhouse plants, in flower.—Messrs. Jackson & Son 1st.

Eight Orchids.—Here the competition was very close, Mr. Bates taking 1st honours with smaller but more evenly flowered plants than his opponents; 2d, Messrs. Jackson. In the first collection was a beautiful example of *Aerides Dayanum*, with a couple of beautiful spikes; and A. Lobbi, 3d, Mr. A. Williams, gr. to J. Bridgeman, Esq., Twickenham.

Eight exotic Ferns.—Mr. D. East, gr. to F. Wigan, Esq., East Sheen, 1st; all his plants were well grown and very fresh. 2d, Mr. J. Cornhill, gr. to J. S. Virtue, Esq., Weybridge.

Six stove and greenhouse plants, in flower.—1st, Mr. Crafter, gr. to the Rev. W. Finch, Kingston Hill; 2d, Mr. Attrill, gr. to C. J. Freake, Esq., Kingston.

Six fine-foliage plants.—Mr. Crafter was also 1st here, and Mr. Attrill 2d.

Six exotic Ferns.—Mr. W. Smith, gr. to A. Cooper, Esq., Twickenham, 1st; Mr. Morell, gr. to J. S. Rutter, Esq., 2d. Twelve hardy Ferns.—Mr. James, gr. to W. Farnell Watson, Esq., Isleworth, 1st; Mr. Crafter 2d.

Pelargoniums were nicely flowered for so late in the season, but the specimens somewhat small. Mr. James took 1st and Messrs. Dobson & Sons 2d in the class for six large-flowered kinds, and also for six fancies.

Table decorations: three stands or vases (open).—1st, Mr. W. Brown, St. Mary's Grove Nursery, Richmond; 2d, Mr. Kinghorn; 3d, Messrs. Dobson & Sons. Three stands or vases (lady amateurs only).—1st, Mrs. A. Chancellor, Richmond; 2d, Mrs. G. Moran; 3d, Miss Augusta M. Warde, Richmond. A single vase (lady amateurs only).—Miss Isabella Warde, Richmond, 1st; Mrs. A. Chancellor, 2d. Hand bouquet (open).—1st, Mr. W. Brown; 2d, Messrs. Dobson & Sons.

Thirty-six Roses, three trusses of each (nurserymen).—1st, Messrs. Paul & Son, the Old Nurseries, Cheshunt; 2d, Mr. C. Turner, the Royal Nurseries, Slough; 3d, Messrs. Dobson & Sons. Twenty-four Roses (nurserymen).—1st, Messrs. Paul & Son; 2d, Mr. C. Turner; 3d, Mr. G. Masters, Weybridge. Twenty-four Roses (amateurs).—1st, Mr. W. Mace, gr. to Captain Eastwick, Teddington; 2d, Mr. Moorman, gr. to the Misses Christy, Kingston.

Fruit was remarkably good, and shown in considerable quantities. For six dishes Mr. Fry, gr. to L. Baker, Esq., Eastcott, was 1st, with a collection, all good; 2d, Mr. G. Cornhill.

Three bunches of black Grapes (open).—1st, Mr. D. East, with moderate sized bunches, the berries large, even, and jet-black; Mr. Bates, who was 2d, had also good bunches, but a little looser. Three bunches of white Grapes (open).—Here Mr. Bates stood 1st, with Foster's Seedling, well coloured; 2d, Mr. Edwards, gr. to Mrs. Tristram, Liphook.

Three bunches of black Grapes (competition limited to the Society's district).—1st, Mr. Bates; 2d, Mr. East. Three bunches white Grapes (Society's district).—1st, Mr. Bates; 2d, Mr. H. Child, gr. to H. G. Smith, Esq.

Special prizes, given by Lady John Chichester for a model garden.—1st, Mr. J. Wells; 2d, Mr. A. J. Ellis, gr. to A. Hicenan, Esq. Given by Lady

Alice Peel for six *Dracenas*.—1st, Mr. Crafter; 2d, Mr. W. Bowell. Given by Sir Trevor Lawrence for six exotic Ferns.—1st, Mr. Smith; 2d, Mr. Bowell. Given by C. T. White, Esq., for twelve Palms.—1st, Mr. Kinghorn; 2d, Mr. Cornhill. Given by W. H. Punchard, Esq., for six Orchids.—1st, Mr. Bates; 2d, Mr. East. Given by A. Cooper, Esq., for the best *Adiantum farleyense*.—1st, Mr. Bates; 2d, Mr. Smith. Given by John Hales, Esq., for six table plants.—1st, Mr. Bates; 2d, Mr. James. Given by Mr. James Wigan for six *Adiantums*.—1st, Mr. Crafter; 2d, Mr. Smith. Given by S. Walker, Esq., for a plant-case furnished.—1st, Miss Augusta M. Warde. Given by the Hon. J. C. W. Vivian for four *Lycopodiums*.—1st, Mr. James; 2d, Mr. Bowell.—Given by H. G. Bohn, Esq., for twenty-four Roses.—1st, Mr. G. Marlow; 2d, Mr. James.

Silver cup given by Messrs. James Carter & Co. for twelve dishes of vegetables.—1st, Mr. Crafter, who showed a very fine collection. Prizegiven by H.S.H. the Duke of Teck, for a set of five window plants, grown by cottagers, artisans, railway servants and labourers in the Society's district.—Mr. J. Saunders and Mr. J. Goodwin were 1st and 2d. Given by Sir Arthur Rugge-Price for a collection of vegetables (cottagers').—Mr. J. Goodwin 1st, Mr. T. B. Giles 2d. Given by Lieutenant-Colonel Burdett for six kinds of vegetables.—1st, Mr. J. Tigwell.

Prizes were awarded to the following nurserymen.—Messrs. Veitch and Sons, Chelsea, who exhibited a very fine group of plants, consisting of *Nepenthes*, *Palms*, *Sarracenias*, *Ferns*, fine-foliage and new plants, interspersed with about thirty *Orchids* in flower, and the handsome *Hydrangea Thomas Hogg*; they had also several boxes of *Roses*; to Messrs. Osborn & Sons, Fulham, who had a very good bank of fine-leaved and variegated plants; to Messrs. Rollisson & Sons, Tooting, for an excellent and beautiful group of flowering and ornamental plants, including the singular *Brassavola Digbyana* in bloom, as also several examples of rare *Odontogloss*; to Mr. Dean, for a large and very effective lot of bedding and herbaceous plants; to Mr. Herbst, for collection of *Palms*, &c.; to Mr. Laing, for cut *Roses*, &c.; to Mr. Turner for *Pinks*. (From a Correspondent.)

Bitterne and West End Horticultural: July 4.—This is a somewhat small show, but a very interesting one to the neighbourhood, always looked forward to and thoroughly enjoyed as a district holiday. Bitterne is a very pleasant suburb of Southampton, with many high-class residences about it, and the gentry take turns in giving the show accommodation in their grounds. On this occasion it was held in the grounds of Moorlands, the residence of Captain H. Sholto Douglas.

The leading exhibitor is Mr. Hazelfoot, of Moor Hill (Mr. N. Blandford, gr.). His leading collection of nine plants comprised *Latania horbonica*, some good *Caladiums*, *Ferns*, &c., all clean and well grown. Mr. Blandford also had the best six stove and greenhouse plants, comprising *Clerodendron Balfourianum*, *Dendrobium nobile*, *Bougainvillea glabra*, *Statiea profusa*, &c. Captain Andrew, R.N., had the second best miscellaneous group of plants, comprising *Adiantum farleyense*, *Croton variegatus*, the variegated *Pine-apple*, &c. Additional groups of plants came from Mr. Hazelfoot and W. S. Gillett, Esq. (Mr. T. Grant, gr.), which greatly helped the display. The plants were generally of good size, well and cleanly grown, as if the exhibitor took pride in displaying them at the local show to the best advantage.

Variegated Pelargoniums were so well done as to be a striking feature. They were sadly wanted at the recent exhibition of the Pelargonium Society in London. The six plants displayed by Mrs. J. J. P. Hoare were perfect specimens, and consisted of Mrs. Turner, very fine; Mrs. John Clutton, Beauty, Prince Silverwings, Italia Unita, and Meteor. The best nine, from Mr. Blandford, were only just inferior, and included Lady Cullum, Lass o' Gowrie, Princess of Wales, Imperatrice Eugénie, Mrs. Turner, and Fascination, in fine condition. Mr. Blandford had by far the best six *Fuchsias*, *Roderick Dhu* and *Rose of Castile* being very fine.

In the way of fruit, Mr. T. Grant had the best four dishes, comprising *Peaches*, *Nectarines*, *Cherries*, and *Strawberries*. He also staged some excellent *Black Hamburgh* and *Muscat of Alexandria Grapes*, and a dish of *Peaches* in a miscellaneous group. Some Sir J. Paxton *Strawberries* contributed by Capt. Andrew, R.N., were particularly fine. Outdoor fruits on the whole illustrated the backwardness of the season.

Good cut *Roses* were shown by Messrs. A. Jackson and W. S. Gillett, and in the class for twelve cut flowers Captain Andrew and Mr. Wilson were placed equal 1st. Vegetables were, on the whole, well shown by gardeners, amateurs, and cottagers; and in the nurserymen's class Mr. J. Kingsbury, Southampton, was the only exhibitor. Some very fine *Sweet Williams* were shown by Mr. Wilson and Mr. Kingsbury, and were Highly Commended.

Stevenage Horticultural: July 5.—Like many other societies, the Stevenage Society seeks in the first instance to encourage cottage gardening in its district, and supplements the work by giving prizes for amateurs and gentlemen's gardeners. The cottagers' produce relatively is generally far ahead of that found in the other divisions, but then it must be said the prizes are small, and scarcely fitted to bring forward good exhibits.

In the cottagers' plant classes prizes are offered for Fuchsias, Pelargoniums, and Calceolarias, and for plants other than those named. The best Calceolaria was one of the herbaceous varieties, of *bona fide* window growth, well-bloomed, and very clean and healthy. Begonias, Cacti, Hydrangeas, &c., were all creditably grown. There was a falling off in the usual quality of fruit and vegetables, consequent upon the lateness of the season.

In the open classes the leading exhibitors of table decorations and cut flowers were Mrs. Geo. Salmon and Captain Fellowes, of cut Roses the Rev. T. H. Gill and Rev. F. G. Jennings; and of vegetables the Rev. J. O. Seager and Captain Fellowes. Collections of wild flowers by cottagers were remarkably good. Among plants were Fuchsias, Palms, Balsams, Coleus, Caladiums, &c. Fruits and vegetables were generally well shown. The exhibition was greatly helped by some boxes of fine cut Roses from Messrs. E. P. Francis & Co., nurserymen, Hertford.

The Weather.

STATE OF THE WEATHER AT BLACKHEATH, LONDON, FOR THE WEEK ENDING WEDNESDAY, JULY 11, 1877.

MONTH AND DAY.	BAROMETER.		TEMPERATURE OF THE AIR.				Hygrometric Deductions from Glaisher's Tables 6th Edition.	WIND.	RAINFALL.

- July 5.—A very fine day. Cool. Heavy clouds, thunder-storm, and heavy rain at 8.30 P.M.
- 6.—Fine day, very cloudy at times. Shower in the afternoon, and frequent thunder heard. Cool.
- 7.—A fine day. Cold. Very dull and showery at times. Thunder and lightning in evening.
- 8.—A dull, cold day: fine at intervals. Slight showers at times.
- 9.—A very cloudy dull day. Few drops of rain at times. Cool.
- 10.—A very fine clear warm day. Strong breeze.
- 11.—A fine cloudy day. Cool breeze. Clear at night.

LONDON: Barometer.—During the week ending Saturday, July 7, in the vicinity of London, the reading of the barometer at the level of the sea decreased from 30.13 inches at the beginning of the week to 29.98 inches by the afternoon of the 2d, increased to 30.03 inches by the morning of the 3d, decreased to 29.88 inches by noon on the 6th, and increased to 30.19 inches by the end of the week. The mean reading for the week at sea level was 30 inches, being 0.17 inch below that of the preceding week, and the same as the average value.

Temperature.—The highest temperatures of the air observed by day ranged between 71½° on the 4th and 63° on the 1st; the mean value for the week was 68½°. The lowest temperatures of the air observed by night varied from 44½° on the 7th to 55° on the 1st; the mean value for the week was 49½°. The mean daily range of temperature in the week was 19½°, the greatest range in the day was 23° on the 3d, and the least 8° on the 1st.

The mean daily temperatures of the air were as follows:—1st, 57° 5; 2d, 59° 3; 3d, 58° 1; 4th, 60° 2; 5th, 57° 7; 6th, 54° 8; 7th, 52° 9; and the departures in defect of their respective averages were:—3° 7, 1° 8, 3° 1, 1° 1, 3° 8, 6° 8, and 8° 9. The mean temperature of the air for the week was 57½°, being 4° 2 below the average of observations extending over a period of sixty years.

The highest readings of a thermometer with blackened bulb in vacuo, placed in sun's rays, were 150½° on the 5th, 144½° on the 4th, and 140° on the 3d;

on the 1st the reading did not rise above 83°. The lowest readings of a thermometer on grass, with its bulb exposed to the sky, were 36½° on the 7th, and 39½° on the 6th; the mean for the seven low readings was 42°.

Wind.—The direction of the wind was W. and S.W., and its strength moderate. The weather during the week was generally fine, but cool and showery, and the sky cloudy. Slight thunderstorms occurred on the 3d, 4th, 5th, 6th, and 7th.

Rain fell on five days during the week; the amount collected was 0.64 inch.

ENGLAND: Temperature.—The highest temperatures of the air observed by day were 80° at Manchester, and 75½° at Nottingham; at Liverpool 64° was the highest temperature in the week. The mean value from all stations was 71½°. The lowest temperatures of the air observed by night were 42° at Sheffield, 42½° at Bristol, Nottingham, and Eccles; at Sunderland 49° was the lowest temperature in the week: the general mean from all stations was 44½°. The range of temperature in the week was the greatest at Manchester, 35°, and the least at Liverpool, 20½°. The mean range from all stations was 27°.

The mean of the seven high day temperatures was the highest at Manchester, 73°, and the lowest at Liverpool, 61½°; the mean value from all stations was 67½°. The mean of the seven low night temperatures was the lowest at Eccles, 45½°, and the highest at Portsmouth, 52½°; the mean from all stations was 49½°. The mean daily range of temperature in the week was the least at Liverpool, 12°, and the greatest at Manchester, 25½°; the mean daily range of temperature from all stations was 18°.

The mean temperature of the air for the week from all stations was 56½°, being 6½° lower than the value for the corresponding week in 1876. The highest was 58½°, at Brighton and Plymouth, and the lowest 52½°, at Eccles.

Rain fell on four or five days in the week at most stations. The amounts varied from 1½ inch at Liverpool, and 1½ inch at Norwich, to one-tenth of an inch at Brighton and Truro. The average fall over the country was half an inch.

The weather during the week was showery, cool, and the sky generally cloudy. Thunderstorms were general during the week at most places.

SCOTLAND: Temperature.—The highest temperatures of the air ranged from 69½° at Aberdeen to 63° at Paisley; the mean value from all stations was 66°. The lowest temperatures of the air varied from 43° at Paisley to 47° at Leith; the general mean from all stations was 44½°. The mean range of temperature in the week from all stations was 21½°.

The mean temperature of the air for the week from all stations was 54½°, being 3° lower than the value for the corresponding week in 1876. The highest was at Dundee, 55½°, and the lowest at Paisley, 53½°.

Rain.—The falls of rain at the various stations ranged from 1 inch at Edinburgh to four-tenths of an inch at Dundee and Paisley; the average fall over the country was six-tenths of an inch.

DUBLIN.—The highest temperature of the air was 69½°, the lowest 40½°, the range 29°, the mean 55½°, and the fall of rain 0.55 inch.

Meteorological Observations made at Blackheath during the Month of June, 1877.—The mean reading of the barometer for the month was 29.846 inches, being 0.033 inch above the average of the preceding thirty-six years. The highest temperature of the air was 84° 7, on the 19th; the lowest temperature 43° 3, on the 17th. The mean high day temperature of the air was 74° 4; the mean low-night temperature was 51° 5; the mean temperature of the air was 61° 4; the mean temperature of the dew-point was 49° 2. The mean of all the highest readings in sun's rays was 132° 8, and the mean amount of cloud was 42.

Rain fell on seven days, the amount collected was 0.64 inch, being 1.30 inch below the average of the preceding sixty-two years. Thunderstorms occurred on the 11th and 12th.

Summary of the wind for the month:—N., four days; E., nine days; S., seven days; and W., ten days.

JAMES GLAISHER.

Variorum.

THE ARCTIC WOODLAND.—Popular impressions are often far from the truth, and in regard to the Arctic regions they are undoubtedly so. A treeless land would be, in the opinion of most people, the idea which would suggest itself in regard to the regions in question. Yet this, though true, is not all the truth. Within the Arctic circle are found trees often forming considerable though stunted forests. In Eastern Siberia Pines and other trees come down almost to the water's edge; while over all Western Siberia, Arctic Russia, and Lapland, the tree limit runs within the Arctic circle; trees extend even to the North

Cape. In Greenland we find, even in the most southerly parts of it, no herbage more worthy of the name of tree than the stunted Birch, which in the more sheltered valleys of that country—equally inappropriately named with Iceland—attain the proportion of little shrubs; and it is not until we come to the milder latitudes of the Pacific that the tree-line, which had described a southerly curve in the cold regions of central North America, again rises to the north, and until we reach the shores of Behring Strait we find nothing which we can dignify by the name of trees. . . . The wooded banks of the Yuku touch the Arctic circle, and forests of white Spruce are found on the Noatak, a river which falls into Eschscholtz Bay, which infringes on the Arctic circle. In Lapland the Spruce ceases at about the sixty-eighth parallel, and the Scotch Fir at the sixty-ninth; but in Norway, owing probably to the presence of the warm Gulf Stream, which sweeps along the coast and into the Arctic Sea—at last far east as Novai Zemlai—we find forests of Scotch Firs 60 feet in height as far north as Altenford, and Birches about 45 feet high in an equally northern latitude. In latitude 70° 28' the hardy Scotch Fir still maintains its ground, though the Spruce fails a degree or so further south. In the vicinity of Hammerfest, a well-known Lapland town, in latitude 70½° N., there are dwarf Alders and Aspens, Bird Cherries, Raspas, and Currants. In the Scandinavian Peninsula, probably also owing to the warmth which a sea, unencumbered, and in addition laved by a current of a higher temperature, affords, Barley is cultivated as far north as the seventieth parallel, the latitude of Disco Island, on the Greenland coast, and Oats up to the sixty-fifth, "in sheltered valleys, where rocks and cliffs reflect the sun's rays with much power." *The Countries of the World.*

WHY THE BAROMETER RISES AND FALLS.—First of all, what is a barometer? It is a tube or pipe, closed at one end and open at the other, and made of some transparent material, such as glass, so that it may be seen through. This tube is filled with the melted metal called mercury, and when quite full the thumb is placed over the open end (so as to keep the mercury from falling out), and the tube is turned upside down. So the closed end is at the top, the open end at the bottom, and if the thumb were removed the mercury would, of course, run out. But now suppose you wished not to waste any, and so put the open end of the tube into a basin with some more mercury in it, and then removed your thumb, what would happen? "Why, the mercury would all run out into the basin," some one will say. But this is a mistake, as the Italian philosopher Torricelli found out; and whatever size or length of tube be taken, the whole of the mercury will not run out, but a length of about 30 inches of the tube will remain full of mercury, and you cannot make it run out into the basin unless you either pull the open end of the tube out of the mercury or make a hole in the closed end of the tube. This puzzled Torricelli for a long time, until at last the thought struck him that the only thing which was on the mercury in the basin was the air, and that it was probably the weight of the air pressing on the metal which prevented its running out into the basin. "If so," thought Torricelli, "then if I take my tube and basin of mercury up a mountain, less and less of the tube will remain full, for there is evidently less air above the basin at the top of the mountain than at the bottom." You may be sure he didn't wait very long before he made the experiment; and to his great delight, he found the mercury getting lower and lower in the tube, thus proving that it really was the weight of the air that kept it in the tube at all; and so the instrument was called a barometer, which is derived from the Greek, and means in plain English, a "weight measurer." But if the barometer is watched it will be found to contain different quantities of mercury on different days. On a fine day the mercury will, as a rule, stand higher in the tube than on a wet day or just before rain; and now for the reason of this. Why does the barometer rise (or, rather, the mercury in it) in fine weather, and fall when it is going to be wet? . . . Now dry air is much heavier than wet air, or air containing steam. The consequence is, that when the air gets moist it becomes lighter, and presses less on the mercury of the barometer, so more mercury flows out into the basin, and, consequently, less remains in the tube, or, as we usually express it, the barometer falls. Now, when the air is very wet, there is, of course, more chance of rain than when it is dry, for rain is formed by the cooling of the steam contained in moist air.—*From "Little Folks" for July.*

Answers to Correspondents.

ALLSPICE: A. The true Allspice is certainly not a pot herb, but the berry-like fruits of *Eugenia Pimenta*, a bushy tree in the West Indies.
BEGONIA AND VIOLA: G. Nixon. There are many finer Begonias than the one you send. The *Viola* is a very pure white, and if vigorous, and a free successive bloomer, would be a valuable bedding plant.

CABBAGE: C. Barnes. Early Barnes would be the same as Early Rainham, but Barnes' Early is a small growing Cabbage which the late William Barnes, of Camberwell, we think, used to catalogue. It very much resembles the small Nonpareil. The two Cabbages are as far apart as well may be. We cannot say where you can get seeds.

CHRYSANTHEMUMS: J. P. A. We cannot say. COLORADO BEETLE: Inquirer. Read our last two numbers.

BRANCH-TUBERS OF POTATO.—A correspondent furnishes us with a fine specimen of this peculiarity. The haulm had been broken nearly in two, and the top had lain on the surface of the ground. A check to the descending sap then was associated with the production of the tubers, and may prove a useful hint.

FIG. 9.—AXILLARY TUBER, POTATO.

Morphologically the case is interesting, as showing that the Potato tuber is merely a thickened shoot.

FUNGUS: A. Sufferer. The fungus is the common dry-rot, Merulius lacrymans, and the cause of its appearance is probably the want of ventilation underneath the floor. The only safe remedy is to take up the boards and relay with new ones, taking care to insert an air-brick, or ventilator, in the exterior wall below the level of the flooring.—C. H. Chester. The minute fungus, which causes such destruction amongst your cuttings, is seen very clearly under the microscope. It belongs to the genus Acremonium, the different members of which group often, when once established, run on and cause great mischief.

INSECTS ON POTATOS: R. L. The common Aphis

FIG. 10.—APHIS VASTATOR.

rapae of Curtis, Aphis vastator of the late Alfred Smee.

INSECTS: T. T. The leaf received is badly infested with the common black fly. Boil 4 oz. of Quassia chips for ten minutes in a gallon of soft water; strain off the chips, and add 4 oz. of soft soap, which should be dissolved in it while cooling. Use when cold. No Aphis can stand a dose of this mixture; but you must test the strength on one or two leaves of such tender things as Cucumbers before you apply it to all.

NAMES OF PLANTS: P. P. Cyrtomium falcatum.—W. K. Reseda luteola (Dyer's-weed).—F. Wilkinson. Please send fresh specimens in a little damp moss. Those we have are too much withered for identification.—A. B. The small yellow Foxglove, Digitalis lutea.—H. T. D. Chelidonium. Agrostis nebulosa.—C. E. F. Ranunculus arvensis.—R. B. z. Silene Armeria; 2. Cotoneaster frigida.—C. Osman. Allium neapolitanum.

SHALLOT: Nomenclature. Allium ascalonicum.

THRIPS ON VINES: A Young Gardener. If carefully in time thrips may be removed from Vines by taking sponging the leaves with a solution of soft soap and tobacco-water, but when a house in which the Grapes are ripe becomes infested the best remedy is persistent

fumigation with good tobacco-paper. Three smokings at intervals of three or four days, will prevent further mischief until your correspondent has cleared off his crop, when the house may again be well smoked and washed with the garden engine to cleanse and preserve the old foliage as long as possible. The taste of tobacco of which he complains, of two evils the least, may be removed in a few hours by abundant ventilation, and frequent damping of paths and floors with cold water. As an additional precaution he might cut a sufficient quantity of Grapes to last a fortnight before he fumigates, and preserve them in a cool room in bottles of water. When the Vines are pruned they should be denuded of all loose bark, well scrubbed with soap and water, and painted with Gishurst Compound—3 oz. to the gallon. The woodwork and walls should also be washed and painted. W. Coleman.

FOREIGN SUBSCRIBERS sending Post-office Orders are requested to make them payable at the post-office, King Street, Covent Garden, London, and at the same time to inform the Publisher at the office of this Journal.

Correspondents are specially requested to address, post-paid, all communications intended for publication to the "Editors," and not to any member of the staff personally. The Editors would also be obliged by such communications being sent as early in the week as possible. Correspondents sending newspapers should be careful to mark the paragraphs they wish us to see. Letters relating to Advertisements, or to the supply of the Paper, should be addressed to the Publisher, and not to the Editors.

Markets.

COVENT GARDEN, July 12.

Next week will see all the soft fruit fairly in, but generally speaking it is of indifferent quality. We have seen the bulk of the Middlesex Strawberries, and the Kent fruit is now beginning to arrive in considerable quantities. Raspberries are a decided improvement, after the rain of last week, and are making high prices. Currants are making a bad sale. Cherries have experienced a decided fall. Trade quiet. James Webber, Wholesale Apple Market.

FRUIT.

Table listing fruit prices: Apricots, per box; Cherries, p. 1/2-sieve; Grapes, per lb.; Lemons, per 100; Melons, each; Oranges, per 100; Peaches, per doz.; Pears, per doz.; Pine-apples, per lb.; Strawberries, p. lb.; Figs, green, each.

VEGETABLES.

Table listing vegetable prices: Artichokes, English; Aubergines, p. doz.; Beans, French (new); Beet, per doz.; Cabbages, per doz.; Carrots, per bunch; Cauliflowers, per doz.; Celery, per bundle; Chilis, per 100; Cucumbers, each; Endives, per doz.; Garlic, per lb.; Gooseberries, green; Herbs, per bunch; Horse Radish, p. bun.; Lettuces, per score; Mint, green, bunch; Mushrooms, per pott.; Onions, 12 bunches; Parsley, per bunch; Parsley, per lb.; Peas, green, p. bun.; Radishes, per bunch; Spinach, per bush; Tomatos, per doz.; Turnips, per bundle; Vegetable Marrows.

CUT FLOWERS.

Table listing cut flower prices: Bouvardias, per bun.; Calceolaria, p. bun.; Carnations, per dozen; Cornflower, 12 bun.; Eschscholtzia, dozen; Eucharis, per doz.; Gardenia, per doz.; Heartsease, 12 bun.; Heliotrope, 12 spr.; Iris, 12 bunches; Lilies (in variety), 12 sprays; Mignonette, 12 bun.; Myosotis, 12 bunch.; Pelargoniums, 12 spr.; Pinks (white and colored); Primula, double, per bunch; Rocket, 12 bunches; Roses (outdoor), 12 bun.; Spiraea, 12 sprays; Stephanotis, 12 spr.; Stocks, 12 bunches; Sweet Peas, 12 bun.; Tropaeolum, 12 bun.

PLANTS IN POTS.

Table listing plants in pots: Balsams, per dozen; Bedding-out plants; Begonias, per doz.; Bouvardias, doz.; Calceolaria, doz.; Clematis, doz.; Clockscombs, per doz.; Coleus, per dozen; Cyperus, doz.; Dracena terminalis; Ferns, in var.; Ficus elastica; Fuchsias, per dozen; Heaths, variety; Heliotrope, per doz.; Hydrangea, per doz.; Lilliums in var.; Mignonette, per doz.; Myosotis, per dozen; Myrtles, doz.; Palms in variety; Pelargoniums; Scarlet, per doz.; Petunias, per doz.; Rhodanthe; Richardia aethiopia; Roses, per dozen; Spiraea; Valotta purpur.

SEEDS.

LONDON: July 11.—The usual summer quietude continues to characterise the trade for farm seeds, and values consequently show no alteration. Perhaps the most noticeable feature of the week has been a speculative inquiry for Trefoil, and also for white Clover seeds; both descriptions promise very badly for next harvest—Trefoil, especially, being thinner than it has been for many years. In red Clover seed no transactions whatever are just now taking place. Trifolium will in all probability be very abundant, and with favourable weather for securing the same, prices will, it is expected, rule low. Winter Tares are reported to look well, but no sales for future delivery have yet taken place. There is a quiet demand for sowing Mustard and Rape seed. The Canary seed trade is without animation. Blue Peas and Haricot Beans find buyers on former terms. John Shaw & Sons, Seed Merchants, 37, Mark Lane, London, E.C.

CORN.

At Mark Lane on Monday English Wheat made an advance of 1s. per quarter as compared with a week back, while foreign was certainly the turn in favour of the seller. Barley met with a quiet sale, at fully recent prices. Malt was very dull, and Oats were not quite so dear. Maize was a shade firmer, while Beans, Peas, and flour were slow, at about late rates. Flour had perhaps a tendency towards further reduction.—On Wednesday the supplies of English Wheat were short, but foreign Wheat was plentiful, and except perhaps as regards Barley and Maize, the arrivals of other kinds of produce was fairly large. No change can be noted in prices from Monday, indispotion to sell at less money constituting the firmness of the market.—Average prices of corn for the week ending July 7:—Wheat, 61s. 5d.; Barley, 35s.; Oats, 27s. 10d. for the corresponding week last year:—Wheat, 48s. 6d.; Barley, 34s. 9d.; Oats, 30s. 3d.

CATTLE.

At Copenhagen Fields on Monday there was a fair demand for beasts, and prices advanced. There were about 300 American in good condition. For sheep the demand was active, and scarcely any alteration in quotations. Choice lambs and calves were in request at fully late rates. Quotations:—Beasts, 45s. 6d., to 55s. 2d., and 5s. 8d. to 6s. 2d.; calves, 5s. to 6s. 4d.; sheep, 5s. 4d. to 5s. 6d., and 5s. 10d. to 6s. 8d.; lambs, 7s. 10s.—On Thursday beasts were in moderate supply, and sold slowly, but the tendency was in favour of buyers. So also as regards sheep; the best breeds fairly maintained late rates, but inferior qualities were lower to sell. Lambs were in good supply, and drooping in value. Calves were lower to sell.

HAY.

At Whitechapel on Tuesday fodder was in steady demand at full prices. The supply was moderate. Prime Clover, 100s. to 140s.; inferior ditto, 85s. to 95s.; prime meadow hay, 90s. to 124s.; inferior ditto, 70s. to 85s.; and straw, 44s. to 57s. per load.—On Thursday the supply on offer was moderate. For good old stuff a fair demand prevailed, but new and inferior qualities were dull. Prices ruled firm. Quotations:—Clover, best, 100s. to 140s.; inferior, 85s. to 90s.; hay, best, 90s. to 124s.; inferior, 70s. to 85s.; and straw, 44s. to 57s. per load.—Cumberland Market quotations:—Superior old meadow hay, 120s. to 132s.; inferior, 100s. to 110s.; new hay, 84s. to 110s.; superior old Clover, 132s. to 140s.; inferior, 110s. to 118s.; new Clover, 90s. to 110s.; and straw, 57s. to 63s. per load.

POTATOS.

At the Borough and Spitalfields Markets the supplies of Potatos continue on a moderate scale, and trade remains steady. New Jersey kidneys, 220s. to 260s.; Cherbourg ditto, 200s. to 230s.; Jersey rounds, 190s. to 220s.; Cherbourg round, 200s. to 220s. per ton. Old Potatos realise from 5s. to 6s. 6d. per cwt.—The imports into London last week comprised 18,464 baskets from Rotterdam, 575 boxes 637 cases and 45 tons from Barleur, 870 cases 727 boxes from Cherbourg, 1096 packages 777 cases and 48 cases from Malta, 169 cases from Palermo, 64 barrels from Hamburg, 33 packages 34 barrels from Boulogne, and 11 barrels from Dunkirk.

COALS.

There was no change in quotations at market either on Monday or Wednesday, but business was steady.—Seaham West Hartley, 15s. 3d.; Walls End—Bishops Close, 15s. 9d.; Hetton, 18s.; Hetton Lyons, 15s. 9d.; Hawthorn, 15s. 9d.; Lambton, 17s. 6d.; South Hetton, 18s.; Vanes, 15s. 9d.; Chilton, 17s.; East Hartlepool 17s. 9d.; Tees, 17s. 9d.

EACH READER of this Paper will be entitled to receive from the NATIONAL FINE ART UNION, 35, Great James Street, London, W. C., a copy (23 in. by 17 in.) of the beautiful Steel-Plate Engraving entitled

THE DAUGHTER OF THE REGIMENT.

(COPYRIGHT.)

This splendid work of art is, without doubt, one of the best JOHN ABSOLON ever painted, and it is engraved, in the finest possible style, upon steel, by that celebrated artist, HENRY LEMON, Esq.

The scene is that of the British Army, encamped before the walls of Sebastopol. Stretching away to the right are the white canvas tents, surmounted by the English Flag, floating proudly in the breeze, while, standing in the foreground, and surrounded by luxuriant foliage, is THE DAUGHTER OF THE REGIMENT. With one arm uplifted, and holding in her hand a glass of spirit, just drawn from the flask at her side, her splendid form is thrown into an attitude of most perfect grace, and she stands, amid the din of battle, the embodiment of all that is noble in human nature. The mixed expression of dashing bravery and tender sympathy so plainly marked upon her countenance proclaims her one of that band of heroes who, throwing on one side the claims of home and kindred, casting to the winds the peaceful happiness of a luxurious life, followed our gallant troops into the field, and encountering every hardship, proved in the midst of the roar of cannon, the tramp of cavalry, and the groans of the wounded, that patience, sympathy, and duty are the qualities of our brave countrywomen. There is no telling how soon our troops may be called upon to engage in a deadly strife, but one thing can be said, that should such a time come, THE DAUGHTER OF THE REGIMENT will be in her place to urge them on to victory, and to succour and help the sick and the wounded. As an historical memento of the CRIMEAN WAR, and as an artistic production, this grand picture stands unrivalled, while its intrinsic worth may be gathered from the following:—

"DEAR SIR,—

"The Engraving of THE DAUGHTER OF THE REGIMENT is Copyright, and has never been sold under the regular price of TWO GUINEAS." (Signed) CHARLES GOOLD, Manager.

"June 8, 1877.

This GRAND PRESENTATION PICTURE will be given to each reader of this paper who cuts out the Redemption Bond found below, and sends it to the NATIONAL FINE ART UNION, 35, GREAT JAMES STREET, LONDON, W. C., together with sixteen stamps, or Post-office Order for 1s. 3d., payable at the General Post-office, London, E. C., to CHARLES GOOLD, to pay the cost of case, transmission, copyright, and other charges. It will then be sent free to all parts of Great Britain and Ireland, securely packed and warranted to reach its destination uninjured.

Cut out this Bond and Send it to the National Fine Art Union, 35, Great James Street, London, W. C.

G. C.	REDEMPTION BOND.
<i>This Bond entitles the holder to One Copy of the beautiful Steel Plate Engraving of</i>	
"THE DAUGHTER OF THE REGIMENT"	
(Copyright),	
And must be sent, together with Sixteen Stamps, or Post Office Order for 1s. 3d., to the	
NATIONAL FINE-ART UNION,	
who will redeem it in the order it is received.	
(Signed)	NATIONAL FINE ART UNION, 35, Great James Street, London, W. C.
N. B.—NOT AVAILABLE AFTER AUGUST 7, 1877	

NOTE THESE INSTRUCTIONS.—All Bonds must be sent in on or before August 7, 1877. The Bond must in all cases be sent. Each Copy will be sent securely packed. One Copy will be sent for each BOND, and NONE CAN BE SENT WITHOUT ONE, EXCEPT ON THE RECEIPT OF TWO GUINEAS. The Bond will not again be printed in this paper, hence the advisability of at once cutting it out and sending it for redemption, as each will be attended to in rotation, as received.

The Picture is well worth handsomely framing, and its artistic merit and intrinsic value will render it a desirable addition to every household.

**THOMAS'S
NEW POULTRY FENCING,**

No. 508.

Very strong and durable. Reduced Prices, 1877.

Galvanised after Manufactured, with Iron Standards, Painted Black, and SPACED 2 FEET APART, rendering it the strongest and best Fence in the Market.

This ornamental Fencing is easily fixed or removed by any labourer, without extra cost.

PRICES:—

6 feet high, 6s. per yard; 7 feet high, 7s. per yard,

Including the Iron Standards and the Bolts and Nuts for securing the Panels to the Standards. Doors are charged 3s. extra, except when 12 yards are ordered, in which case a door is included.

Five per cent. discount allowed for prompt cash on Orders amounting to 40s. and upwards.

Illustrated and Priced Catalogues of every description of Horticultural Wirework on application.

NEIGHBOUR'S Celebrated BEEHIVES. PHILADELPHIA EXHIBITION, 1876.

PARIS EXHIBITION, 1867.

Three Silver Prize Medals awarded George Neighbour & Sons. The only English exhibitors who obtained Silver Medals for Beehives.

The IMPROVED COTTAGE BEEHIVE, as originally introduced by G. Neighbour & Sons, working three bell-glasses, is neatly and strongly made of straw; it has three windows in the lower hive. This Hive will be found to possess many practical advantages, and is more easy of management than any other Beehive that has been introduced.

Price, complete £1 15 0
Stand for ditto 0 10 6

The LIGURIAN or ITALIAN ALP BEE being much in repute, G. N. & SONS supply a Swarm of Bees with genuine Italian Queen, in the Improved Cottage Hive, at £4, Hive included.
An Italian Alp Queen, with full directions for uniting to Black Stocks, 15s. each.

ENGLISH BEES.—Stocks and Swarms may be obtained as heretofore.
THE APIARY. By A. NEIGHBOUR. 5s., postage 4d.
A newly arranged Catalogue of other improved Hives, with Drawings and Prices, sent on receipt of two stamps.
GEO. NEIGHBOUR AND SONS, 127, High Holborn, W.C., or 149, Regent Street, London, W.

JONES'S PATENT "DOUBLE L" SADDLE BOILER.

These Boilers possess all the advantages of the old Saddle Boiler, with the following improvements—viz., the water-space at back and over top of saddle increases the heating surface to such an extent that a "PATENT DOUBLE L SADDLE BOILER" will do about twice the amount of work with the same quantity of fuel; the cost of setting is also considerably reduced, and likewise the space occupied; at the same time these Boilers are simple in construction, and being made of wrought iron are not liable to crack. They are made of the following sizes:—

High.	Wide.	Long.	To heat of 4-in. Pipe.	Feet.	£ s. d.
20 in.	18 "	18 "		300	7 0 0
20 "	18 "	24 "		400	8 0 0
20 "	18 "	30 "		500	9 0 0
24 "	24 "	24 "		700	12 0 0
24 "	24 "	30 "		850	14 0 0
24 "	24 "	36 "		1,000	16 0 0
24 "	24 "	42 "		1,400	20 0 0
28 "	28 "	60 "		1,800	25 0 0

Larger sizes if required.

From Mr. CHARLES YOUNG, Nurseries, Balham Hill, S.W., May 20, 1877.

"Having given your Patent 'Double L' Boilers a fair trial at my Nurseries, I beg to say that they are most satisfactory. I consider them the best in use, and without doubt the most economical of all boilers; they will burn the refuse of other tubular boilers I have in work."

PRICE LISTS of HOT-WATER PIPES and CONNECTIONS, with Boilers, of all sizes and shapes; or ESTIMATES for HOT-WATER APPARATUS, erected complete, will be sent on application.

J. JONES AND SONS, Iron Merchants, 6, Bankside, Southwark, London, S.E.
Who ordering Boilers please refer to the above advertisement.

AGRICULTURAL LOCOMOTIVES,

STEAM PLOUGHING MACHINERY, ROAD LOCOMOTIVES, TRAMWAY LOCOMOTIVES, STEAM ROAD ROLLERS.

For Prices, Description, and Reports of Working, apply to the Manufacturers,

AVELING & PORTER, ROCHESTER, KENT; 72, CANNON ST., LONDON, E.C.; and 6, AVENUE MONTAIGNE, PARIS.

AVELING & PORTER'S ENGINES have gained the highest Prizes at every important International Exhibition. The two Medals for Progress and Merit were awarded them at Vienna for their STEAM ROLLERS and ROAD LOCOMOTIVES; and at the last trials of the Royal Agricultural Society of England their AGRICULTURAL LOCOMOTIVES gained the First Prize after exhaustive trials, when one of their 10-horse power Engines, fitted with single slide and ordinary link-motion, indicated 35-horse power, with a consumption of *but one-fifth pounds of coal per horse-power per hour.*

AN EXTRAORDINARY BOILER.—

During the Great Boiler Contest at Birmingham, in 1872, all Boilers were severely tested to prove their respective merits. One test was, "How long can each Boiler go without Night Attention?" However, one Boiler proved this to a surprising degree, as after being shut up for twelve hours (from 9 P.M. to 9 A.M.), it still retained its heat in 1000 feet of 4-inch pipes, and yet had more than 1 bushel of fire drawn from its furnace in the morning—equal, in point of fact, to seventeen hours of continuous firing. What a boon to Gardeners. This was THE CHAMPION, Deards' Patent Close-Coil Boiler, for Drawings and Prices of which send two stamps to

Messrs. DEARDS, Boiler Works, Harlow, who now have their Boilers at work in every county of England except three. Amateurs will also find THE WONDER, a smaller kind of Boiler, equally as satisfactory, and certainly "the best thing" out. Awarded five First Prize Silver Medals.

RUSTIC Garden Furniture IN GREAT VARIETY.

Garden Seats, Awnings and Tents, Rustic Tables, Chairs, and Flower Stands, Lawn Mowers, Garden Rollers, Water Barrows, Wheelbarrows, Garden Tools, Fancy Wirework, Birdcages, Hammocks, and all kinds of Garden Furniture at lowest marked prices.

CATALOGUES POST-FREE. THE PANKLIBANON, 56, BAKER STREET, W.

For Sale, a STEVENS' IMPROVED TRENTHAM WROUGHT IRON HORTICULTURAL BOILER, 6 feet long by 3 feet diameter, fitted with Inlet and two Outlet Pipes, Fire-door and Gate complete. For price and particulars apply to HILL AND SMITH, Brierley Hill Ironworks, Dudley.

STEVENS' TRENTHAM GREENHOUSE BOILER,

After long experience, has proved the most SIMPLE, ECONOMICAL, EFFECTUAL, and LASTING BOILER extant; recently improved. For Illustrations, with full particulars, apply to the Sole Makers,

F. & J. SILVESTER, HOT-WATER ENGINEERS, &c., &c. Castle Hill Works, Newcastle, Staffordshire.

Our Boilers are the ONLY ones made with the sanction and under the inspection of the inventor, Mr. Stevens—all others being base imitations.

GREEN'S PATENT "SILENS MESSOR,"
Or Noiseless Lawn-mowing, Rolling, and Collecting Machines for 1877.
The Winner of every Prize in all cases of competition.

The superiority of these Machines over those of all other makers is universally acknowledged. They will Cut either long or short Grass, Bents, &c., wet or dry. These advantages no other Lawn Mowers possess. They are the simplest in construction, the easiest to work, the least liable to get out of order, make little noise when in use, and are the most durable Lawn Mowers extant. The largest stock of Mowers kept in London is to be found at our Establishment, 54 and 55, Blackfriars Road, where purchasers can select from upwards of 500 machines of hand, pony, and horse power, and have their orders executed the same day they are received. Every Lawn Mower sent out is guaranteed to give entire satisfaction, otherwise it may be returned at once free of cost to the Purchaser. N.B.—Those who have Lawn Mowers to repair will do well to send them either to our Leeds or London Establishment, where they will have prompt attention, as an Efficient Staff of Workmen is kept at both places. Descriptive Illustrated Price List free on application.

GREEN'S PATENT ROLLERS
For Lawns, Drives, Bowling Greens, Cricket Fields, and Gravel Paths.
SUITABLE FOR HAND OR HORSE POWER.

They can be had of all respectable Ironmongers and Seedsmen in the United Kingdom; or direct from the Manufacturers, **THOMAS GREEN & SON,** SMITHFIELD IRONWORKS, LEEDS; And 54 and 55, BLACKFRIARS ROAD, LONDON, S.E.

Oil Paint No Longer Necessary.

HILL AND SMITH'S BLACK VARNISH for Preserving Ironwork, Wood, or Stone. This Varnish is an excellent substitute for oil paint on all outdoor work, while it is fully two-thirds cheaper. It was introduced upwards of thirty years ago by the advertisers, and its genuine good quality, notwithstanding a host of unprincipled imitators, is fully attested by its constantly increasing sale. It may be applied by an ordinary labourer, requires no mixing or thinning, and is used cold. It is used in the grounds at Windsor Castle, Kew Gardens, and at the seats of many hundreds of the Nobility and Gentry, from whom the most flattering testimonials have been received, which HILL & SMITH will forward on application. Sold in casks of about 30 gallons each, at 1s. 6d. per gallon, at the Manufactory, or 1s. 8d. per gallon carriage paid to any Station in the Kingdom.

UNSOLICITED TESTIMONIAL RECEIVED MAY 3, 1877. "The Ryleys, Alderly Edge, Manchester.—Messrs. Hill & Smith.—Sir,—For some 20 years I have used your 'Black Varnish,' and shall be glad if you will forward me another cask, as I consider it the best thing known for the preservation of all outdoor works, either wood or iron, that requires to be painted.—Yours respectfully, ALBERT LOWE, F.R.S." Apply to HILL and SMITH, Brierley Hill Ironworks, near Dudley; and 118, Queen Victoria Street, London, E.C., from whom only it can be obtained. CAUTION.—It having lately come to the knowledge of HILL & SMITH that spurious imitations of this Varnish are being offered by unprincipled dealers at a slight reduction in price, they would especially draw attention to the fact that every cask of their Varnish is legibly marked with their name and address, without which none is genuine.

CARSONS' PAINT,
PATRONISED BY THE QUEEN, H.R.H. THE PRINCE OF WALES, H.R.H. THE DUKE OF EDINBURGH, The British, Indian and Colonial Governments, 10,000 of the Nobility, Gentry, and Clergy, Railway and Canal Companies, Collieries, Ironmasters, &c., &c., Is extensively used for all kinds of **OUTDOOR WORK.** It is especially applicable to **WOOD, IRON, BRICK, STONE & COMPO.** CAN BE LAID ON BY UNSKILLED LABOUR. Sold in all Colours. 2 cwt. free to all Stations. Prices, Patterns, and Testimonials Post Free.

London: BRADBURY, AGNEW, AND CO., Bouverie Street, E.C.

ADVERTISERS are requested to note that although we do not object to receive Letters to be called for, we cannot undertake to forward them.

PARTNERSHIP.—A Nurseryman, carrying on a successful business within 25 miles of London, is desirous of meeting with a Partner. Failing health causes Advertiser to wish to find a man, or men who in, say, one or two years would be able to take over from him the entire business. Money would be required, but every facility be afforded provided substantial guarantees were given. The fullest references given and required.—Address, by letter, giving outline of means and position, NURSERYMAN, Messrs. Norris, Allens & Carter, Solicitors, 20, Bedford Row, London, W.C.

WANTED, a HEAD GARDENER, Single, or a Widower, not under 40 years of age, thoroughly competent in the Management of Stove and Greenhouse Plants, also accustomed to Work a Tubular Boiler. Must have a good character for honesty and sobriety.—Apply by letter, stating wages, &c., required, to W. L., 39, Railway Road, King's Lynn, Norfolk.

WANTED, IMMEDIATELY, a HEAD WORKING GARDENER, where one other is kept; he must thoroughly understand the profession in all its branches, more especially Grape Growing and Management of an Orchard House. No one need apply who cannot produce satisfactory testimonials as to character and competency.—Apply, in the first instance by letter, stating particulars and wages required, to H. H. C., 47, William Street, Woolwich.

WANTED, a GARDENER; Wife to undertake the Laundry Work.—Reply, stating wages required, and full particulars, to R. T. CUNNINGHAM, 155, Cannon Street, London, E.C.

WANTED, an active, steady Man, of good address, as GROUND FOREMAN; must be well up to the Value and Culture of Trees, Shrubs, Evergreens, and Conifers especially. A man without family preferred. Wages, 30s. per week and house. Also a young Man as an ASSISTANT PROPAGATOR, in the Houses. Wages, 21s. per week, to begin with.—Apply, with full particulars in each case, to JOHN SHAW AND CO., Stamford Nursery, Bowdon, Cheshire.

WANTED, a thoroughly practical MAN, to propagate grafted and own-root Roses under Glass, and a few Hardy Conifers, in a first-class London Nursery. Every encouragement and a good salary will be given to a good man.—X. Y. Z., *Gardeners' Chronicle* Office, W.C.

WANTED, an IMPROVER, under Glass; one who has had some experience preferred. A first-rate opening. Premium required.—Apply, by letter, to FRANCIS & ARTHUR DICKSON & SONS, The Upton Nurseries, Chester.

WANTED, a Young MAN, of good character, accustomed to Indoor Work, to Assist in the Houses.—State wages and all particulars to H. BOYCE, Clapham Road Nursery, S.W.

MESSRS. WILLIAM CUTBUSH AND SON require, at their Barnet Nurseries, a Young MAN to Assist the Propagator in the Houses.—Reply, stating where previously employed, age, wages, &c., Highgate Nurseries, London, N.

Seed Trade.

WANTED, an intelligent, respectable young MAN, with some experience, in a small Retail Shop, and to make out Invoices, &c.—State age, reference, and wages, to JAMES HIRD, Nurseryman, Downham.

WANT PLACES.

Head Gardeners.

JOHN LAING AND CO. can at present recommend with every confidence several energetic and practical Men, of tested ability and first-rate character. Ladies and Gentlemen in WANT of GARDENERS and BAILIFFS, or GARDENERS for First-rate Establishments, or Steward and Situations, can be suited, and have full particulars by applying at Stanstead Park and Rutland Park Nurseries, Forest Hill, London, S.E.

E. G. HENDERSON AND SON have many excellent GARDENERS with approved testimonials for ability now waiting in their Nurseries for re-engagement.

E. G. H. & S. will be pleased to answer any enquiries from Noblemen and Gentlemen requiring such.—Fine-apple Nursery, Maida Vale, London, W.

B. S. WILLIAMS, having at the present time several very excellent GARDENERS upon his Register, is desirous of placing them in Situations where great experience and trust are required. B. S. W. would at the same time beg to intimate that when a Gardener is applied for that the filling of the situation should be left with him, as that would prevent unnecessary correspondence and delay.—Victoria and Paradise Nurseries, Upper Holloway, London, N.

GARDENER (HEAD).—Age 27, single; thoroughly experienced in all branches of the profession, including Orchids. Good character from last employer.—G., Stock's House, Peckleton, Hinckley.

GARDENER (HEAD).—Single; thoroughly understands Orchids, Ferns, Vines, Melons, Stove and Greenhouse Plants, &c. Ten years' good references.—G. WATERMAN, Crix, Hatfield Feverel, Chelmsford.

GARDENER (HEAD).—Age 28, single; thoroughly experienced in all the different branches of Horticulture. First-class recommendations.—H. J. W., Glanton, Alnwick, Northumberland.

GARDENER (HEAD).—Age 31, married, no family; thorough practical knowledge of the profession in all branches. Excellent character.—A., T. Jackson & Son, Nurserymen, Kingston, Surrey.

To Noblemen and Gentlemen.

New South Wales or New Zealand.

TO MERCHANTS, ACCOUNTANTS, AGRICULTURISTS, and OTHERS.—A young Man (age 25) leaving for the Colonies is desirous of obtaining an engagement. Good knowledge of Corn, Seeds, and Plants, and also of Book-keeping. First-class character and references.—COLONIAL, Albert Cottage, Clifton View, Bedminster, Bristol.

KINAHAN'S LL WHISKY. Kinahan & Co., finding that, through the recommendation of the Medical Profession, the demand for their CELEBRATED OLD LL WHISKY for purely medicinal purposes is very great, submit with pleasure the following Analysis by Dr. Hassall:—"I have very carefully and fully analysed samples of this well-known and popular Whisky. The samples were soft and mellow to the taste, aromatic and ethereal to the smell. The Whisky must be pronounced to be pure, well-matured, and of very excellent quality. The Medical Profession may feel full confidence in the purity and quality of this Whisky."
20, Great Titchfield Street, Oxford Street, London, W.

ELLIS'S RUTHIN WATERS.

PURE AERATED WATERS.

ELLIS'S RUTHIN WATERS.—Crystal Springs, Soda, Potass, Seltzer, Lemonade, Lithia, and for Gout, Lithia and Potass. Corks branded "R. ELLIS AND SON, RUTHIN," and every Label bears their Trade Mark. DINNEFORD'S FLUID MAGNESIA.

The best remedy for ACIDITY of the STOMACH, HEADACHE, GOUT, and INDIGESTION; and the safest aperient for delicate Constitutions, Ladies, Children, and Infants.
DINNEFORD AND CO.,
172, New Bond Street, London, and all Chemists.

COMPLETE, CONCISE INSTRUCTIONS FOR BOWEL COMPLAINTS AND DIARRHOEA.—When these diseases prevail, immediate recourse should be had to HOLLOWAY'S OINTMENT, which should be rubbed two or three times daily over the abdomen till the intestinal irritation subsides. All inflammation will be subdued and excessive action restrained. This treatment, assisted by judicious doses of HOLLOWAY'S PILLS, is applicable to all forms of Diarrhoea and Dysentery, attended by heart sickness, griping flatulency, and other distressing and dangerous symptoms. After rubbing in the Ointment a flannel bander should be worn, and the patient should be restricted to a farinaceous diet for a few days till the urgency of the disease has been diminished by the persevering employment of these remedies.

SUTTON'S
IMPROVED STRAIN
OF
CALCEOLARIA
"PERFECTION."

After many years' careful selection we have succeeded in producing a strain of Calceolaria which, for beauty and form of flower, richness of colour and habit of plant, is acknowledged to be one of the finest in cultivation.

Price, 3s. 6d. per Packet, post-free.

From "THE GARDEN," June 2, 1877.

"The Calceolarias at Messrs. Sutton & Sons' Nurseries, Reading, are just now beautifully in bloom, and should be seen by all who take an interest in this class of plant.

From "THE GARDENERS' CHRONICLE," June 2, 1877.

"A remarkable collection of Calceolarias is now in bloom at Messrs. Sutton & Sons' Nursery, Reading. The house, which is of good size, is ever crowded with specimen plants, but it serves to show off their great beauty and attractiveness en masse.

From MR. B. BARIHAM, Gr. to the Right Hon. the Earl of Sefton.

"It affords me great pleasure to be able to inform you that your Calceolaria seed has given extreme satisfaction. I have just now in flower one of the finest lots of hybrid Calceolarias it has ever been my lot to look upon.

From "THE GARDENERS' MAGAZINE," June 2, 1877.

"The strain of Calceolarias distributed by Messrs. Sutton has flower-leaves of immense size and perfect in contour. The flowers, which are borne in huge clusters, are of immense size and of the finest possible shape, and embrace every colour.

From A. E. RUSSELL, Esq., Dalnabreck.

"My Calceolaria plants from seed purchased of you last year are particularly fine, of very compact habit, and beautiful in colour."

From MR. W. GEARLE, Gr. to R. M. Jaques, Esq., Easby Abbey.

"I have some very fine Calceolarias from seed supplied by you; they are the admiration of all who see them."

Table with two columns: Left column lists 'JAMES' INTERNATIONAL PRIZE CALCEOLARIA' and 'SUTTON'S SUPERB CINERARIA'. Right column lists 'SUTTON'S PRIZE CYCLAMEN' and 'SUTTON'S PRIZE PRIMULA'. Includes pricing in shillings and pence.

 The Queen's Seedsmen, Reading.

LOMARIA GIBBA.—Good Plants in 48's, fit for immediate sale—about 5 dozen cheap.
R. FARRANCE, Florist, Chadwell Heath, Essex.

LILY OF THE VALLEY.—I beg to inform all my numerous Customers, buyers of the above, that the Roots are unusually fine this year, and that I can furnish extra strong flowering roots at 4s. per 1000, carriage free to London. Orders are requested as early as possible.
ROBERT NEWMANN, Nurseries, Erfurt, Prussia.

CATALOGUES.—His Excellency Pierre Wolkenstein will feel greatly obliged if Nurserymen and Seedsmen will kindly send him their Catalogues. They should be forwarded (by post) to
S. E. PIERRE WOLKENSTEIN, Secrétaire de la Société Impériale d'Horticulture de Russie, St. Petersburg.

VANDA LOWII.—A magnificent specimen, 5 feet high, twenty-two leaves, strong break five leaves; bore two spikes of bloom last season, 7 to 8 feet long. Also a few plants of the magnificent new HYBRID DENDROBIUM, "Ainsworth," shown in a great state of perfection at the late Manchester Exhibition: *vide Gardeners' Chronicle*, June 9, page 710; and June 26, page 730. Prices on application to
GEORGE TOLL, 358, Stretford Road, Manchester.

The Best Hardy Bedding Plant.
CLEMATIS JACKMANII.—Flowers rich purple, 4 inches across, and so profuse as to completely cover the bed. Begins to bloom in June, and continues until severe frost. It is perfectly hardy, and the stools improve annually. The only secret of success is a rich soil, to keep up free growth. Strong plants in pots, 12s. per dozen; extra strong plants, 2 years old, 18s. per dozen. Other sorts of Clematis and Climbers in great variety. Descriptive LIST on application.
RICHARD SMITH, Nurseryman, Worcester.

COCOANUT FIBRE REFUSE may be had at 1s. per 4-bushel bag, bag included; a truck, 250 bushels, £1 5s.; one-horse load may be had at the factory, 2s., by sending for it.
M. GAREY, 57, Old Montague Street, Whitechapel, E.

COCOANUT FIBRE REFUSE, invaluable for Gardening purposes. One thousand testimonials. Four-bushel bag, 1s., bag included; truck-load, loose, free to any Rail, 25s.
POTTER OYLER, Spitalfields Market, N.E.

COCOANUT FIBRE REFUSE, newly made.—Reduced price, in 4 bushel bags, at 1s., bags included; 100, 20s.; or Truck-load, 25s. Delivered free to any rail in London.
J. STEVENS AND CO., Fibre Works, Greyhound Yard, 134, High Street, Battersea, S.W.

Fibrous Peat for Orchids, &c.
BROWN FIBROUS PEAT, best quality for Orchids, Stove Plants, &c., £6 6s. per truck. **BLACK FIBROUS PEAT,** for Rhododendrons, Azaleas, Heaths, American Plant Beds, 17s. per ton. Delivered on rail at Blackwater, S. E. R., or Farnborough, S. W. R., by the truck-load. Sample sack, 5s. 6d. each. Fresh SPHAGNUM, 10s. 6d. per sack.
WALKER AND CO., Farnborough Station, Hants.

SCOTT'S WASP DESTROYER.—The only preparation made for thoroughly destroying Wasps, large Piles, &c. Sold in bottles, at 1s. 6d., 2s. 6d., and 5s. each. The larger sizes are the cheapest. May be obtained through any Seedsmen, or direct from
JOHN SCOTT, The Royal Seed Stores, Yeovil.

SIMPSON'S RED SPIDER, THRIPS, &c., ANTI-DOSE. Testimonials of the highest order on application. Per quart, condensed, 6s.; per pint, 3s. 6d. Supplied to Seedsmen and Chemists. Strongly recommended in the *Gardener*, and by many first-class Gardeners.
 Prepared by **JOHN KILNER,** Wortley, near Sheffield.

GISHURST COMPOUND.—Used by many of the leading Gardeners since 1859, against Red Spider, Mildew, Thrips, Greenfly, and other Blight in solutions of from 1 to 2 ounces to the gallon of soft water, and of from 1 to 16 ounces as a winter dressing for Vines and Fruit Trees. Has outlived many preparations intended to supersede it. Sold Retail by Seedsmen, in Boxes, 1s., 3s., and 10s. 6d. Wholesale by **PRICE'S PATENT CANDLE COMPANY** (Limited).

PRICKLY COMFREY (SYMPHYTUM ASPERRIMUM). Whole Roots purchased by

It is perhaps the most complete list ever published of these articles.

SALES BY AUCTION.

Great Clearance Sale of Nursery Stock at the HAMMERSMITH NURSERY. MR. J. C. STEVENS has received instructions from Messrs. Lec. to offer for SALE by AUCTION, on the Premises, at the Hammersmith Nurseries, Hammersmith, W., on TUESDAY, July 24, and following days, at half-past 12 o'clock precisely each day, the third and concluding portion of STOVE and GREENHOUSE PLANTS, together with the GREENHOUSES, PITS, BOILERS, &c., the land being required for building purposes. On view the day prior and mornings of Sale, and Catalogues had at the Nursery, and of Mr. J. C. STEVENS, Auctioneer, 38, King Street, Covent Garden, W.C.

Orchids. MR. J. C. STEVENS will SELL by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on THURSDAY, July 26, at half-past 12 o'clock precisely, an importation of fine Plants of IONOPSIS FANICULATA, COLIA JUGOSUS, BURLINGTONIA FRAGRANS, ONCIDIUM FORBESII, O. CRISPUM, O. SARCODES, O. DIVARICATUM, SOPHRONITES VIOLACEA, ZYGOPETALUM CRINITUM, &c.; some Established ORCHIDS, and some Plants of ODONTOGLOSSUM CRISPUM, COLOGNYE CORRUGATA, C. GLANDULOSA, C. BARBATA, LÆLIA ANCEPS, L. ALBIDA, L. AUTUMNALIS, ONCIDIUM MARSHALLIANUM, &c. On view the morning of Sale, and Catalogues had.

Houghton Estate. ANNUAL TIMBER SALE.—Twelve miles from Lynn, ten from Fakenham, and seven from Snettisham Railway Stations.

WILLIAM C. HOPKING is favoured with instructions from the Most Noble the Marquis of Cholmondeley, to SELL by AUCTION, on WEDNESDAY, July 25, 200 splendid OAK TIMBERS, many of which are 30 to 40 feet in length, of great girth and very clean. 130 ASH TIMBERS, and 14 ELM TIMBERS, some of which are 40 feet in length. A large quantity of OAK WRONGS, about 20,000 HARDWOOD EAGGOTS, and two large STACKS of BARK, the produce of the entire fell for this season of 282 Oak Timbers. The Bark is secured in very good order, and is of the best quality.

The Auctioneer has particular pleasure in calling the attention of Timber Merchants and the purchasers of Bark to the above-described Sale, it being the finest fell of timber offered for Public Competition on the Estate for many years.

Sale to commence at 10.30 punctually, in the Park, close by the road leading from Bircham to Rudham.

A Conveyance will leave the Globe Hotel, King's Lynn, and Fakenham Station at 8.30 o'clock for the convenience of Purchasers.

Catalogues may be had a fortnight previous to the Sale on application to W. FREUER, Esq., Estate Agent, West Rudham, Brandon; or to the Auctioneer, Great Bircham, Lynn, Norfolk.

Lowdham, near Nottingham.

MR. J. H. BRADWELL will SELL by AUCTION, at the Black Boy Hotel, Long Row, Nottingham, on WEDNESDAY, August 8, at 4 o'clock in the afternoon, subject to such conditions of sale as will then be declared, the following valuable FREEHOLD PROPERTY. All that Dwelling-house and Shop situated at Lowdham, Notts, with the Bakehouse, Stable, Cartshed, Cowhouse, and other outbuildings thereto belonging; also the large and productive Gardens, adjoining the aforesaid premises, with two Vineries, Cucumber Pit, &c., all late in the occupation of Mr. John Dabell, deceased; also all those three Cottages or tenements and Gardens adjoining. The above premises contain, including the site of the buildings, 2 a, 2 r, or thereabouts, are situate in the centre of the thriving village of Lowdham, and is well worth the attention of Nurserymen and Market Gardeners, the gardens having been largely stocked by the late owner with choice and well selected Fruit Trees of every description, and being within a short distance of the Midland Railway station, and easy reach of the town of Nottingham.

Further particulars of the AUCTIONEER, Nottingham and Southwell; or, Mr. STENTON, Solicitor, Southwell.

On WEDNESDAY, August 1, 1877, in the Town Hall of Bruges, Belgium, between the hours of 11 A.M. and 6 P.M.,

**DANIELS BROS.,
ROYAL NORFOLK SEED ESTABLISHMENT,
Norwich.**

**THE NEW SEEDLING ROSE,
"QUEEN of BEDDERS"
(NOBLE).**

See Coloured Plate (after Mrs. Duffield), "Gardeners' Chronicle," May 5, 1877.

Perhaps the finest of all the English Seedling Roses of recent introduction. It is far excellence a really Bedding Rose in every sense of the word—requires no pegging down, support, or training of any kind, and is a continuous early and late bloomer.

First-class Certificate Royal Horticultural Society, August 2, 1876.

Its inflorescence may be imagined when it is stated that a plant 18 inches high had eighty-four buds and expanded flowers upon it on September 6, 1876.

A constant supply of buds was obtained from early June to November of that year—over five months.

Good Plants are now being sent out in strict rotation at 10s. 6d. each.

Coloured Plates 1s. each.

CHARLES NOBLE, BAGSHOT.

TEA SCENTED ROSES.

SPECIAL CULTURE.

We have this season devoted nearly the whole extent of our Glass-houses to the Culture of Tea-Scented and other Roses, and are now enabled to offer plants of very superior quality.

PLANTS, in 5-inch pots, suitable for planting out, 15s. to 18s. per dozen.

.. extra size, in 6-inch pots, for Greenhouse, set with buds, 24s. per dozen.

.. extra size, in 8-inch pots, for Greenhouse, set with buds, 30s. to 36s. per dozen.

.. Half Specimens, 5s. to 7s. 6d. each.

NEW FRENCH ROSES of 1877, 30s. per dozen.

HYBRID PERPETUAL ROSES, established in 9 and 10-inch pots, now showing for bloom, 36s. to 42s. per dozen.

M. LOUIS VAN HOUTTE,
ROYAL NURSERY, GHENT, BELGIUM,
BEGS TO ANNOUNCE THAT HIS
BULB CATALOGUE, NO. 173 T.T., FOR THIS SEASON,

Is now ready, and will be dispatched to his numerous Customers.

Those not receiving the same may apply either to him or his Agents, Messrs. R. SILBERRAD AND SON, 5, Harp Lane, Great Tower Street, London, E.C., when a copy will be sent immediately, post-paid.

The CATALOGUE contains, as usual, an immense assortment of HYACINTHS, TULIPS, CROCUSES, NARCISSUS, and other FLOWER-ROOTS, as also a Selection of Miscellaneous HARDY, TUBEROUS, and BULBOUS-ROOTED PLANTS, and a Supplement of STOVE and GREENHOUSE PLANTS, &c. Our this season's Bulbs are, especially the Hyacinths (contrary to the general expectation), exceptionally fine, healthy, and sound, and cannot be surpassed, if equalled.

The CATALOGUE, No. 174 U.U., is in the Printer's hands, and will appear next month. It will contain a great variety of INDIAN AZALEAS and CAMELLIAS, to which several new ones, of great merit, have been added. Also HARDY GHENT and MOLLIS AZALEAS, HARDY and GREENHOUSE RHODODENDRONS, and a Descriptive LIST of large SPECIMEN CAMELLIAS, &c.

TREE FERNS.

THE LARGEST AND BEST STOCK IN EUROPE.

NEW ENGLISH-RAISED SEEDLING ROSES.

MESSRS. BELL & SON,
THE NORWICH NURSERIES,

Are now executing orders for their TWO NEW ROSES, raised at their Nurseries, and described and announced below. They have been thoroughly tested here before being sent out, and can be recommended with confidence as really distinct novelties.

CLIMBING ROSE "CATHERINE BELL."

Very large flowers of a deep rose colour, the backs of the petals a delicate silvery pink, of exquisite shape and very fragrant. It is very free-flowering, and of vigorous climbing habit, making shoots 6 feet to 8 feet long in one season. Figured in *The Garden*, March 18, 1876.

"Your Rose Catherine Bell is both *belle et grande*."—Rev. Canon Reynolds Hole.

Good Flowering Plants, in Pots, 10s. 6d. each.

COLOURED PLATES ONE SHILLING EACH.

HYBRID TEA ROSE "MRS. OPIE."

Bright salmon-rose, tea-scented flowers, with shell-like petals, a most distinct and novel shade of colour among Tea Roses. It will form a charming companion to Madame Falcot, and will be as extensively cultivated as that variety when well known. In flower from May to November. Figured in the *Floral Magazine*.

Good Flowering Plants, in Pots 7s. 6d. each.

SATURDAY, JULY 21, 1877.

CLIVEDEN.

IF we were asked to select an estate which should combine every requisite that might fairly be expected in a nobleman's residence, where every comfort and every convenience should be allied to beauty and variety of scenery, delightful gardens, leafy woods, bold cliffs and flowing water, we should not have to hesitate a moment. Cliveden (or Cliefden, as it was formerly written), the Buckinghamshire seat of His Grace the Duke of Westminster, combines all these, and is, moreover, within an hour or so of London. Larger domains there may be—this feature may be more imposing in one place, that in another—but take it for all in all Cliveden stands out a veritable gem. Its situation and surroundings account for this in a large measure, but they have been so skilfully and tastefully turned to account that one finds it difficult which the most to admire—the entrancing scenery of Nature or the admirable art, which, never obtruding itself, has set forth Nature's beauties to the greater advantage. The Cliveden estate occupies an elevated plateau on the chalk some 300 acres in extent. It lies a few miles distant from Taplow and Maidenhead, and is bounded by the Taplow Court, Dropmore, and Hedsor estates, and for a great part of its extent by the River Thames. On the one side is a steep cliff overhanging the river, richly draped with Clematis, and where the sinuous roots of aged Yews hang on for very life, like so many pythons. On the other sides are woods, rich, deep, glorious, pierced with openings to let in the distant views, and traversed by green paths and noble avenues. Between the two are spacious lawns surrounding the mansion, with its terraces, greenhouses, fruit-houses, and other offices.

Cliefden was built by George Villiers, the profligate Duke of Buckingham, the friend of Charles II., a man whose character has been sketched by many, from Dryden to Macaulay, but never in clearer outline than by the first-named, who speaks of Buckingham as—

"A man so various that he seemed to be
Not one, but all mankind's epitome:
Stiff in opinion, always in the wrong,
Was everything by fits and nothing long;
But in the course of one revolving moon
Was chemist, statesman, fiddler and buffoon;
Then all for women, painting, rhyming, drinking,
Besides a thousand freaks that died in thinking."

Pope refers to the same versatile profligate in some lines commemorative of one of the many incidents of his career, and wherein mention is specially made of

"Cliefden's proud alcove,
The abode of wanton Shrewsbury and of love,"

in allusion to the intrigue of the Duke and the Countess of Shrewsbury. The Countess was as unprincipled as the Duke himself, if not worse, for it is recorded of her that in the guise of a page she held the Duke's horse while he killed her husband in a duel—a story we should be glad, for the credit of human nature, if some historian of the future would kindly prove to be untrue.

Poetical justice, however, has befallen Buckingham in more senses than one, as witness the following lines relating to him:—

' Mark where in ruins lies the last retreat of motley Villiers.

Here sunk in sorrow and deprived of all
They saw him greatly live and meanly fall."

"In the worst inn's worst room, with mat half hung,
The floors of plaster, and the walls of dung,
On once a flock bed, but repaired with straw,
With tape-tied curtains never meant to draw,
The George and Garter dangling from that bed,
Where tawdry yellow strove with dirty red,
Great Villiers lies."

The poets have, we suspect, secured a longer, or at least a more widely spread, remembrance to this unprincipled man (who died in 1688) than the historians could have done.

The mansion was added to by the first Earl of Orkney, who occupied it until 1735. Frederick, Prince of Wales, occupied it until 1756, and it was during his tenancy that a poet and a musician contributed to encourage and stimulate the patriotic feelings of Britons as much—nay, much more—than the treacheries and faithlessness of Buckingham served to humiliate and depress them, for it was in a chambered vault underneath the dining-room at Cliveden that it was first authoritatively pronounced (in 1740) that "Britannia rules the waves," and that "Britons never will be slaves"—the occasion being the performance for the first time of the *Masque of Liberty*, written by James Thomson, and containing the now well-known song, set to music by Dr. Arne.

Villiers' house was burnt in 1795, owing to the carelessness of a maid-servant addicted to the practice of novel reading in bed. The estate was purchased by Sir George Warrender in 1822 or 1823, and the mansion was rebuilt by him in 1830. In 1849 it was purchased by the late Duke of Sutherland, and shared the fate of its predecessor in November of the same year. The present mansion was completed in 1851, in the Italian style. It was designed by Sir Charles Barry for the late Duke of Sutherland, to whom, as to the fine taste of the late Duchess, much of the beauty of Cliveden is due. The property was purchased by the Duke of Westminster in 1869, and since his occupation many improvements have been carried out. The terraced front, shown in our illustration (fig. 14, p. 76), is nearly 400 feet in length and 26 feet in width, and overlooks a noble sward bedecked with flower beds, and which is reached by a handsome flight of steps, gracefully and naturally draped with climbers. The entrance front of the mansion on the opposite side is recessed, somewhat after the fashion of Versailles. On one side is an elegant campanile, and near it, but screened from view, are the various offices and the forcing houses and vineries, &c. On the opposite side of the mansion are the conservatories and glazed corridors, the former not in keeping with the rest of the building, and destined probably to be replaced by a structure more in consonance with the fine proportions and elegant design of the mansion, and with the requirements of its inmates.

THE FLOWER GARDEN.

We have already alluded to this as situated in front of the terraced walk. From this walk a noble view is obtained not only of the flower-garden but of the distant country beyond. The flower garden occupies a nearly level space or plateau of 5 acres. It was first laid out in 1852-53 by Mr. Fleming, the present garden superintendent, after a variety of designs by various landscape gardeners had been considered and rejected as unsuitable. The general design may be seen from our illustration (fig. 15, p. 77), and was suggested by the flower gardens at Versailles. The large space, and simplicity of the design, produce a very imposing effect, and carry the eye on to the lovely English scenery in the distance. Spring bedding, as it is termed, received its first great impulse, about twenty years ago, from the

way in which it was and is still carried out here, with yearly increasing efficiency. Many of our gardening readers must be familiar with the masses of softened colour, harmonising one with another and set off so exquisitely by the broad sweeps of grass. The refined taste of the late Duchess of Sutherland found ample scope here, indeed throughout the grounds evidences of her taste are apparent.

Opposite the north side of the mansion runs a noble avenue more than 460 yards in length, and fittingly terminated by a statue of the late Duke of Sutherland. This fine avenue is 50 yards in width, of which the central gravelled roadway occupies 13 yards.

The river boundary of the estate, formed by the cliff we have already spoken of, is of singular and varied beauty. Our illustrations may serve to give some idea of the loveliness of the scenery in this portion of the grounds. Wordy descriptions always fail in their object, and convey no adequate idea to the mind of the reader. Suffice it to say, that our illustration (fig. 13, p. 73) is taken from the top of the cliff in an opening looking towards Cookham, and made through the dense wood, 100 feet or so above the water, which here makes a sinuous bend in front of the observer. Another view (fig. 16, p. 81), from the top of the Yew-beclutched, Clematis-bedecked bank, looks towards Maidenhead. At the top of the cliff here is a long cloistered walk with Yew o'erhung, stretching nearly 300 yards, and at the base by the river are winding walks o'ertopped by noble trees, brakes and thickets full of wild flowers, and a crystal spring whose virtues are known to the many visitors whom the Duke's generous good feeling permits to visit this delicious nook. Hard by is a rustic *châlet* fitted with all the requirements necessary for *al fresco* entertainments, and which is also put at the service of the visitors on certain occasions. "The Springs" have for many years been a very favourite resort for pic-nic parties, as the following impromptu verses written on the spot, about the beginning of the present century, by the author of *Ireland's Thames*, amply testifies—

"Secure from summer's sultry ray,
Haste hither swains and with you bring
Your ladies *debonnaire* and gay,
To taste of Cliefden's cooling spring.
Here bow'ring shades to love invite,
And realise the poet's dream;
Here Thames allures the ravish'd sight,
While murmuring glides cool Cliefden's spring.
Gay Ovid of his nymphs may write,
With quill fresh pluck'd from Fancy's wing,
Yet here from Nature I'll indite
The charms of Cliefden's cooling spring.
Let Horace too his nectar boast,
And be the juicy Grape his theme,
Yet here in bev'rage cool I'll toast
The nymph of Cliefden's cooling stream.
Nor will I scorn young Bacchus' aid,
While she is here for whom I sing:
He shall beneath this fragrant shade
Infuse his Grape in Cliefden's spring.
If here the sigh of love prevails,
The dart of envy finds no sting;
Old Thames will smile and tell no tales
Of what is done at Cliefden's spring."

The illustration, fig. 18, p. 84, is taken from quite another part of the ground, and shows a beautiful grass slope of large extent looking towards Ascot, and backed with woods on either hand, and with a few masses of Rhododendrons and flowering shrubs in the foreground. The extent of this long stretch of grass gives it a peculiarly impressive appearance. With excellent taste the woodland walks, and here and there the grass slopes, are left almost entirely to Nature, and are studded with wild flowers in rich profusion; which, seen thus in their natural setting, lose nothing in comparison with their more fashionably attired sisters in the dressed garden. Each in its own place is appropriate, and each

viewed from its own surroundings, delights and satisfies the spectator.

Since Cliveden became the property of the Duke of Westminster, the glass department, which is very extensive, as needs must be to meet the large demands made upon it for fruits and flowers, has been entirely re-modelled and re-built, and now forms one of the most compact and complete departments of its kind to be found in the three kingdoms. To Mr. Fleming the credit of the design is due, and a word of praise must also be given to Mr. Gray, of Chelsea, for the substantial manner in which it was carried out by him.

A reference to the ground-plan (fig. 11) on p. 71, which we have given to scale, together with a section of each house and frame, will show at a glance the completeness of the place. The situation is due south, and beginning in the southern left-hand corner we have, 1, the large bothy dining-room; and, 2, the bothy kitchen, above which are the young men's sleeping quarters—altogether one of the very best and most comfortable bothies it has been our good fortune to see in any garden. No. 4 contains the boilers—two of Stevens' Improved Cornish—which heat the whole of the houses, and, as Mr. Fleming testifies, in a most satisfactory manner. Next comes an exotic fernery, No. 5, containing a capital assortment of the most useful subjects for cutting and general decorative purposes rather than a representative collection of species. This house is reached from No. 6, a long corridor, entered from the lawn, and from which access is gained to all the houses. Fruit and flowers here grow side by side, the former predominating, and providing a capital lot of fruits, such as Grapes, Figs, and Cherries, while at the same time affording an agreeable amount of shade. Nos. 7 and 8 are frames used for every conceivable purpose to which such handy structures can be applied. No. 9 is a late Peach-house, in which the trees are trained in the usual manner under the glass, the sorts planted being Grosse Mignonne, Walburton Admirable, and Royal George, the last-named being planted in the centre, and intended eventually to fill the house. The trees are in fine health, and carrying a nice crop of fruit, which will shortly be ripe. No. 10 is a very useful span-roofed pit, and 11 is the Muscat-house, in which, with the exception of single rods of Napoleon and Buckland Sweetwater, Muscat of Alexandria only is grown. The Vines are planted inside, but the roots have ready access to an outside border. Though planted but a few years ago the house is well filled with good bearing wood, and the crop which the Vines are now carrying is the best that we have seen this year, and an uncommonly good one. 12 is a late vinery, in which are canes of Gros Colman, Black Alicante, and Lady Downe's—old Vines that were removed hence from another house, but which, not having thriven since so well as could be desired, are to make way for young ones. No. 13 is an early vinery, from which the crop had been removed. The number of canes is about a dozen, and all but one are Black Hamburgs, the exception being Royal Ascot. The next house, No. 14, is the second vinery, in which the young canes are making a good growth, and the sorts planted are Black Hamburg and Foster's Seedling. No. 15 is an Apricot-house, the only sort grown being Moor Park. No. 16 is a long vinery, which comes in third in succession, and contains only Black Hamburgs—young canes just filling the house, and carrying a capital crop of good useful fruit. The next compartment in this range, 17, is the Fig-house, in which are grown such varieties as Brown Turkey, White Marseilles, and the fine Negro Largo, raised here by Mr. Fleming. The plants are all planted out, some in front and trained under the roof, the others in square brick divisions, and grown in the bush form along the back—all being in rare health and most productive of good fruit. Next comes a handy structure, No. 18, in which Tea Roses are planted

against the back wall, and trained up under the roof, the house also being used in a general-utility sort of manner for the culture of various decorative plants. No. 19 shows a Melon range in four divisions. The first and third compartments from the Rose-house end are occupied with Melons at the present time. Those in the first division are rapidly developing to the ripening stage, and the crop is certainly a very heavy one. The plants are planted out in a bed, as is also the case in the second compartment; only green and white-fleshed Melons are grown at Cliveden, and the sorts in cultivation now are Golden Perfection, Cox's Golden Gem, Victory of Bath, and a useful sort distinguished as a cross with the last-named. In the other compartments are a group of Egg-plants grown solely for decorative purposes, a useful collection of Epiphyllums and other free-flowering sorts of Cactuses, and some young Vines for future planting out elsewhere.

In No. 20 we have a plant stove, span-roofed, and sunk a few feet below the level of the others. A brick pit runs down the centre, and shelves all round the sides. Here are to be seen the usual order of flowering and fine-foliaged subjects, all, with few exceptions, being grown specially on account of their usefulness either for table decoration in their entirety, or for furnishing cut flowers. There is also a small collection of Orchids, and at the present time the greatest amount of flowers are found on Allamandas, Achimenes, and Gloxinias. No. 21 is a span-roofed pit used in spring in the raising of early vegetables, and at other times for general plant culture; 22 is Mr. Fleming's office, 23 is a packing-shed, and 25 a potting-shed, the compartment between them, 24, having a glass roof and front facing north, and being filled with a collection of good-sized specimen Azaleas. No. 26 is the earliest house of Peaches and Nectarines, planted with Downton and Violette Hâtive Nectarines, and Noblesse, Royal George, and Early Beatrice Peaches—the last named being the earliest of all by quite a fortnight. No. 27 is the second Peach-house, containing such varieties as Téton de Venus and Belle Bauce; and 28 and 29 are employed mainly in the culture of Pelargoniums and Carnations, the latter being especially well done, and affording great quantities of fragrant blooms. No. 30 is devoted exclusively to Gardenias and Stephanotis, the former planted out in a bed, and the latter trained thinly up the roof. No. 39 is a Cucumber-house, containing at present robust and thriving plants of Monro's Duke of Edinburgh, and the old Kirklees Hall Defiance; and 32 is an intermediate house, turned to useful account in a variety of ways.

There is no regular kitchen garden at Cliveden, and all, or nearly all, the vegetables, for which at certain seasons the demand is very large, are grown under field culture on the home farm, which also includes a circular piece of about 2 acres devoted almost exclusively to Strawberries.

The high standing of Mr. Fleming in the gardening profession, and his courteous attention to visitors, are so well known that it seems almost needless to refer to such matters; nevertheless it is but common justice to him to say that the skill of a master hand is apparent in every department of the garden.

Illustrations of different views at Cliveden, prepared from photographs specially taken by Mr. Arthur E. Smith, will be found on pp. 73, 76, 77, 81, and 84.

New Garden Plants.

CALOCHORTUS VENUSTUS VARS. LILACINUS AND PURPUREUS, Baker.

These are two very fine varieties of *C. venustus*, which certainly for horticultural purposes deserve a name, which have been sent to me along with a fine series of the typical white-flowered form, as figured by Bentham in the first volume of the new series of the *Horticultural Transactions*, tab. 15, fig. 3, and of *C. splendens* and *C. luteus*, by Messrs. E. H. Krelage & Son, of Haarlem. *Lilacinus* has a distinct red-brown blotch bordered with yellow, and deep purple markings on a pale lilac ground on the face of the sepals, and deltoid petals 2 inches long and broad, plain lilac in the upper half, with a round, red-brown blotch in the centre a third of an inch across, bordered with a bright yellow, and stained with light brown at

FIG. 11.—PLAN OF THE GLASS DEPARTMENT AT CLIVEDEN. (FOR REFERENCES SEE P. 70, OPPOSITE.)

the top, and the lower half of the petal grained with claret-brown, with a crescent-shaped cushion of redder hairs above the naked claw, and outside of this scattered longer, deflexed, more bristly hairs of the same kind. In purpureus the colouring of the naked upper half of the petal is a most brilliant purple-lilac, the central yellow-bordered blotch being not round, but considerably broader than deep, and the graining of the lower half of petal still purple, but less bright.

In *C. splendens*, which must not be confused with *venustus* var. *lilacinus*, there is no central yellow-bordered blotch to the petal, and not a crescent-shaped cluster of hairs, but a small dense pad of short lilac hairs at the very base of the claw, and larger, deflexed, more bristly hairs scattered over the lower half of the petal, the colouring of which is a bright uniform lilac. The motive of these deflexed bristly hairs on the face of the petals of these plants is evidently to facilitate fertilisation by insects. The flower in this *Mariposa* section of *Calochortus* is erect, and the top of the anthers only just reaches to the stigmas, so that without insects fertilisation could hardly take place. The flowers when expanded are bell-shaped in the lower half. Before the pollen is ready the anthers, which, like the filaments, are just like those of a Tulip, stand erect in close proximity to the clavate ovary, but when the pollen is ready they divaricate back against the petals, so that if a bee enters the flower these bristly hairs inevitably cause it to shake the anther considerably, and carry away some of the pollen dusted over its body. *F. G. Baker.*

CATTELEYA WILSONIANA, n. sp. (n. hybr.?)*

This elegant *Cattleya* has flowered twice in the garden of Mr. John H. Wilson, Liverpool. It has been discovered by Mr. E. Dukinfield Jones, who gathered it in company with the old *C. bicolor*, Lindl. There is not much doubt left that it ought to be regarded as a natural hybrid between this and perhaps *C. intermedia*, Grah., since neither the colour nor the asperities of the lip remind me of *C. guttata*, Lindl., whose growth it nearly has. The best shoot is more than 1 foot high, according to a sketch sent by its discoverer. No doubt there was a spathe, but I did not obtain one. The flower is equal to that of a well developed *C. bicolor*. The sepals and petals are of a beautiful deep purple; the lip white, with a yellow blotch at the base, a violet disk in front, and violet angular side laciniae. The anterior lamina, excepting its white claw, is of a very rich beautiful purplish hue. The column is a light whitish purple. It is named in memory of Mr. John H. Wilson at the wish of the discoverer, Mr. Dukinfield Jones. *H. G. Rehb. f.*

EXPERIMENTS ON THE FLOW OF THE SAP.†

BEFORE entering on the subject of this paper, it may be useful to mention—not for this committee, but for the benefit of the outside world, who may read it elsewhere—that they will find an admirable account of the present state of opinion of the scientific world on the various questions connected with the sap, which I am about to discuss, in a series of papers that were published by Dr. Masters in the columns of the *Gardeners' Chronicle* in 1874. On some he expresses himself with hesitation, on others with more confidence, on none with dogmatism, but on all he gives the full gist of the opinions generally received at the date of his writing.

At the beginning of this session I drew the attention of this committee to the course of the sap, being of opinion that recent researches rendered some modification in our views necessary on that subject.

The proposition that I submitted to the committee was, pure and simple, that there was no such thing as descent of the sap at all, but that its course was always upwards. I found the committee quite in accord with me, so far as regarded anything like circulation. I think most of them, if not all, repudiated any belief in the old theory of the ascent of the sap by the fibro-vascular bundles of the wood and its descent by the cellular layers of the inner bark; but I found the majority still imbued by the theories of Sachs, and holding with him, and on his grounds, that descent by some means was absolutely necessary, in respect that assimilation could only take place in the light, and consequently that the whole of that function must be performed in the leaf, whence the assimilated matter there produced must be

transported in some way or other to the other parts of the plant in which it is found; and as these are lower down, and some of them even underground, as in the case of tubers, it followed that there must be a descent in some way or other, and the prevailing opinion seemed to be, as was I think first suggested by Mr. Herbert Spencer, that this took place by a slow swaying, or wandering motion, by means of endosmose and exosmose, through the walls of the cells, which imperceptibly and independent of the current of the sap mixed the whole up together, or carried the different ingredients to where they were wanted.

Since I last spoke on the subject I have endeavoured to see if actual experiment would throw any light upon it, and as a contribution to its elucidation I have now the honour to submit to the committee the particulars of one or two experiments that I have made.

I made experiments with the Vine, the Fig, the Horse Chestnut, and the Hyacinth, but as they all, so far as they went, tended in the same direction, I shall speak principally from the Vine, which was much more manageable, and more readily took up my infusions than any of the others. Thanks to the experiments of Professors M'Nab and Church, I knew of the virtues of lithia as an easily absorbed agent, whose presence could be detected anywhere by the spectroscope in however small a quantity it might be present, and I had the advantage of Pro-

FIG. 12.

fessor Church's own kind assistance in determining for me whether it was present or not. As lithia, however, is colourless, I added to my infusions enough of litmus to colour them deeply, and I am bound to record as the result of my own experience that the lithia told me nothing that the litmus did not equally well. The combination of both, no doubt, adds to the confidence with which I can trust to my experiments, but the litmus had one great advantage over the lithia—that it might be easily handled, and dropped or spilt, without interfering with the experiment; whereas with lithia we have constantly to be on our guard against any careless dispersal of it—as, for instance, by allowing a drop to spill on the bark, or by using a knife that has been employed in cutting a portion of a branch that has been lithiated to cut one that has not. The form and proportion in which I used the lithia were 5 grains of citrate of lithia to each fluid ounce. To this I added a little glycerine, with the view of equalising the specific gravity of the mixture with that of the sap, and then as much as I found necessary of small lumps of litmus. I need not say that I did not evolve these chemical details out of my own inner consciousness. I got them from my friend Professor Church, of Cirencester, who is my tower of strength in any chemical difficulty.

I may add, for the benefit of any outsider who wishes to repeat my experiments or make similar ones, that I got the citrate of lithia from Messrs. Hopkin & Williams, wholesale chemists, Cross Street, Hatton Garden; that its price is 1s. 6d. an ounce (480 grs.), and that litmus is 3d. per ounce. I note this because I rather object to the kind of grandiose way we have

got into of treating cost as too inferior a matter to be worthy of note, whereas, when we have put off our public robes, no one can dispute that cost is a vital consideration with us all. Whether a man has the income of an emperor or of a beggar he has still to ask himself whether he can afford what he is about to do.

I then passed gutta-percha funnels (see fig. 12) over the shoots to be experimented on, and secured them as cups, with the shoots growing up the middle, by means of cork and tallow. I tried waterproof cloth, but it did not hold in, but the gutta-percha funnels did perfectly. My experiments were made in April and May, when the leaves were beginning to open. I put one cup on the stem of the Vine. It held perfectly, and no escape of the liquid took place. After the cup was properly luted to the stem with tallow I cut a nick in the bark a little above the fitting (fig. 12, A), and then filled the cup with the lithiated litmus-mixture, so as to cover the nick. I then allowed it to remain on for six weeks, constantly renewing the mixture in the cup as it disappeared.

After the expiration of six weeks I took up the plant and examined it: and here let me see that the committee and I are in accord as to what I should have found had Sachs' theory been well founded. I imagine that upon every principle I should, on the ordinary principles of gravitation, have found the severed vessels below the nick, and on the same side as it, filled with the infusion in consequence of its descent. So far as regarded that part of the plant it was no longer a closed tube, and there could be no ascent, but being, as it were, merely an open tube, whatever was poured into it should simply find its way to the bottom. And so in fact it did—the infusion below the nick descended to the very fibrils of the roots. In like manner, the part above the nick being a closed tube—closed by the cup at the bottom and by the leaves acting as a sucker at the top—we should expect that the infusion would ascend; and so it did, nearly as completely as it descended below the nick. But how as regards the parts that were on the opposite side from the nick. According to Sachs' theory, whether you call it the result of metastasis or of endosmose and exosmose, the infusion should have been found extravasated and infiltrated through that side, both above the nick and below the nick and up the ascending branches, and in fact everywhere a little; but in point of fact there was not the slightest extravasation nor a solitary particle of lithia or litmus in any of these places. The depth of the nick was the measure of the extent of the penetration of the infusion, and it was as sharply defined as a line could be; and this is just what I said should be the case.

I said that the rapidity of the current would prevent any intermingling of ingredients by endosmose or exosmose, just as a small boat finds a difficulty in getting into the current of a heady river, even with the external aid of oars, or a small stream pouring with the force of gravitation into a more powerful one is shoved aside and driven down the banks. The sap has neither oars nor gravity by which to force its way from one part of the ascending current to another, and it must be content to go with the flow of that part of which it is a component particle. At night there can be no ascending current, for the force that produces it, the sun, is withdrawn, but the tube is full and in equilibrium.

To keep strictly within my experiences, I must explain that this is the result of all my experiments as regards litmus, and of all but that on the Vine as regards lithia. The experiment as to lithia in the uncut side of the Vine could not be tested, because I sent Professor Church the portions of the plant to be tested, all cut up transversely, asking him to cut certain specified ones longitudinally, and then test them separately; but he explained that that would be a delusive test after the portions had travelled from London to Cirencester, for the lithia would have had time to pass by endosmose and exosmose from one side to the other, after the plant was cut in pieces—which of course it would, for there was no longer any current to prevent its infiltration; but the distribution of the litmus when the plant was newly cut showed clearly enough what the result of a search for lithia would have been at that time.

To my mind this is conclusive on the question. Sachs must be wrong; and we must now re-examine his arguments, and see where the flaw lies. If the committee will allow me a few minutes, I do not think we shall have very far to seek. His position is thus stated in his *Physiologie Vegetale*.

* *Cattleya Wilsoniana*.—Caulis gracillimo elato; foliis oblongo-ligulatis acutis geminis; spathe—; pedunculo unifloro (plurifloro?); sepalis oblongis acutis; tepalibus multo latioribus cuneato-oblongis acutis; labello trifido, lacinias lateralibus triangularibus, lacinia media cuneata obovata.—Epidendrum Wilsonianum. *H. G. Rehb. f.*

† Read at a meeting of the Scientific Committee on Tuesday last.

FIG. 13.—VIEW FROM THE CLIFF AT CLIVEDEN, LOOKING TOWARDS COOKHAM. (SEE P. 69.)

"The absolute necessity (says he) of the intervention of light for assimilation in plants with chlorophyll is proved directly by their mode of development in darkness. When we cause seeds to germinate in such conditions, roots, internodes and leaves are developed generally in proportion to the mass of the seed. When all the provision of elaborated principles contained in it are exhausted the development ceases. If up to that period the seed is allowed to germinate in the light, and it is then removed into darkness, the result is the same—the young leaves, although green, assimilate nothing; but if they are allowed to remain long enough in the light to have assimilated a little, there will be developed in darkness leaves and internodes until that new provision be exhausted also."

But there is one important fact that Sachs omits to keep in view here. If the plant in darkness assimilates nothing, neither does it take any food to assimilate. It is well known that plants do not feed in the dark, and nothing is easier than to prove it by experiment. Let any one with a Hyacinth growing in water in a glass, mark by a thread or narrow strip of paper glued to the glass the height at which the water stands at night, he will find it at the same height to-morrow morning, but very different to-morrow night. But the fact is not disputed.

Now on what ground are we to hold that the reason why the plant does not assimilate is the absence of light in preference to the absence of food? Either will account for it, and one will suit Sachs' theory, but the other not. No doubt the food is not taken up because of the absence of light, but it may very well be that if the plant were placed in light so that it could take food generally, and some portions of it were secluded in darkness, we should find that assimilation went on as well in those in the dark as in those exposed to light; and this, in fact, is just what Nature does with tubers. They are in darkness while the plant is in light, and they contain assimilated matter in as great abundance as any Apple in the blaze of sunshine. Now I object to a question of that kind, or, indeed, any other kind, being answered by giving the thing to be proved as part of the proof; but this is what Sachs does. He has to prove that assimilation cannot take place except in light. I offer an instance of its apparently taking place in darkness, and the reply is that that cannot be, because assimilation cannot take place in darkness. It is not that the fire will not burn because it is dark, but that it stops burning when the coals are consumed, because no more are supplied to it. During the day the light and heat of the sun draw up the sap to all the terminal parts of the plants, such as the axial extremities of the branches, the buds, the leaves, the tubers (which are only subterranean buds), where it is partly evaporated and partly assimilated—and as it is used up the roots absorb a corresponding flow to supply the consumption; but at night, when the motive power is withdrawn, the upward flow of sap ceases, the roots become inactive, and cease to feed; at the same time there is nothing to hinder growth going on—it may pile cell upon cell, whether the machine is working or not, and it does so, but assimilation ceases. Sachs has founded an accessory with a principle, and mistaken an effect for a cause.

Allow me, however, further to cite a well known fact in favour of my views, which it reflects no credit upon us not to have sooner so interpreted. Here am I narrating, and you listening to my clumsy experiments, and yet we have all had always before our eyes—and our ancestors for ages have had them before theirs too—a constant series of beautiful and conclusive experiments, proving much more clearly than I have done what I have attempted to show. I allude to what we see in the case of grafts. We know that the stock has certain properties differing from those of the scion. We all know that the properties of the stock affect the scion. They are carried up into its system, but those of the scion are not carried down into the stock. If the theory of descent and wandering and mixing of the sap were true the qualities of the scion ought to descend just as much as those of the stock ascend, but they do not. But some one may say, "Oh, but you are wrong; there are cases in which the influence of the scion has made itself felt on the stock." How many? I ask. Out of the myriads of millions of grafts that are made every year we hear perhaps once in a decade of some single plant where there is a doubtful appearance of a scion having had some influence on a stock, or, rather, on a shoot from one. Now, if I disputed the fact altogether of such an influ-

ence ever having been truly seen, I think I should have plenty of supporters, and I am not sure that I should not be in the right, but I am not careful to do this thing. I am willing to take it as possible that such a thing may have, and that such a thing has occurred, but I add that it is still capable of explanation in accordance with my interpretation of the flow of the sap. It will be observed that such cases have never been recorded until after the lapse of a winter after the grafting, and, in fact, it is nearly impossible that they could. Now although I maintain that there is no descent of the sap, I never did (and could not) deny that there is a period (winter) when it no longer flows at all. The liquid part of the sap is evaporated, the more solid part is dried up, deposited or crystallised, or what is called "stored up" for next year. I imagine that this takes place pretty much simultaneously all through the plant, so that there is little sinking of the column of sap in the vessels. But it is possible that under conditions when there is an unusually large supply of sap in the vessels at the approach of winter, or in plants whose vessels are favourably constructed for it, there may be something like a disturbance of equilibrium, which will allow a portion of the sap belonging to the scion to ebb, as it were, below the graft, and, being there stored up and redissolved, and carried up next year, may give rise to the doubtful phenomenon of which I speak; but I take my stand, not upon exceptions, but on the broad basis of an all but universal experience throughout the whole world.

I meant to have stopped here, but I am in the position of a man, who, having begun to take a rotten beam out of an old house, finds a whole superstructure of dependencies, offsets, and rookeries tumbling about his ears. The system of vegetable physiology now in credence was built upon the faith of the existence of a circulation of the sap, and everything has by degrees been arranged to fit neatly into it. That rotten beam was removed and its place supplied by Sachs' theory; that, I think, I have shown to be rotten too, and in removing it, without having any other props to put in its place, down must come the hypothesis that the plant derives all its carbon from carbonic acid in the atmosphere or its nitrogen from free uncombined nitrogen, through the leaves, and, of course, all power of taking anything into the system through the leaves, and all hypotheses of feeding, whether vegetarian or carnivorous, through these organs. Those theories of circulation by inhibition, diastasis, endosmosis, and exosmosis, to me are already defunct. Six weeks' unavailing effort to get the slightest indication of any of these phenomena in the living plant seem enough for me. The current is steadily upward, and not only permits nothing to come down against it, but is too powerful to permit anything to deviate from its own place, and force its way into another, even by uniting with it on the way upwards. My position is, that for a plant to absorb carbonic acid, whether free or combined, through the leaves for the purpose of supplying it with that important element involves a physical impossibility, and yet this is one of the best received vegeto-physiological hypotheses. It has the advantage of giving a glimpse of an explanation how plants may have first originated. They consist of carbon, nitrogen, and mineral ingredients, besides oxygen, which may be derived from the latter. It is open then to say that plants derive their mineral constituents from the degradation of rocks, and their carbon and nitrogen from the atmosphere—and some plants (as lichens) may. But when we come to test the hypotheses by common sense and common experience they tell us all that you may try to grow a plant in mineral ingredients and leave it to get its carbon from the atmosphere as much as you like but it won't grow. As far as common people can see it will only thrive in humus, in other words where its roots can draw carbon from the organic matters already elaborated in the soil by the long-continued accumulation of past ages. But Sachs states it very broadly. "The fact is unquestionable," says he, "partly established by direct researches on vegetation, partly inferred from the circumstances under which many plants live in a natural condition, that most plants which contain chlorophyll (e.g., our cereal crops, Beans, Tobacco, Sunflower, many saxicolous lichens, Algae, and other water plants obtain" (through the leaves—he does not say so here—but it is implied, and is of the essence of his theory) "the entire quantity of their carbon by the decomposition of atmospheric carbon dioxide, and require for their nutrition no other compound of carbon from without." (Sachs' *Text Book* (Bennett's Trans.), p. 620)

Now in the first place one of the principal of the circumstances to which he certainly above alludes must be the influence of light on assimilation, his interpretation of which I have endeavoured to relate. Next I may mention another phenomenon which seems to me equally adverse to his views, viz., that the plants of which we are speaking exhale oxygen during the day and carbon during the night. If carbon in whatever form passes up from the root to the leaves during the day, and a chemical decomposition takes place whereby it or other ingredients are altered in their way oxygen must be liberated, and after being carried on with the stream of sap will be set free when it reaches the leaves, while the carbon will be used up in the plant; and this is just what takes place by day. But at night, when no feeding or assimilation is going on, no chemical action takes place either, but the carbonic acid with which the sap is charged escapes through the thin cuticle of the leaf as from a vessel left uncovered without any interchange of oxygen at all.

As to the experiments referred to by Professor Sachs, I believe the principal one was made by De Saussure about the beginning of this century (1805), but unhappily I have been unable to see the paper containing it. I know no recent experiments with carbon. As recorded, Saussure's experiment proved that plants in sunlight increase in their amounts of carbon, hydrogen, and oxygen at the expense of carbonic acid and water. But there is no indication whether he attempted to determine whether the carbon was taken up by the leaves or the roots; and as that was not what he was trying to find out, I am disposed to infer that no precautions were taken to decide that point. He seems to have been very careful in measuring the contents and constituents of the air, the plant, and the earth; but as it is plain from that very fact that they were all three subjected to the same experiment at the same time, I do not imagine that the experiment could touch our point.

It must not be inferred that I dispute altogether the possibility of the air supplying a portion of its carbon to the plant. Carbonic acid may be carried down into the earth by showers, and there put in a fit condition for the plant which may then take it up by the roots. All that I say is, that it does not enter free into the plant through the leaves, and that the idea of its descending from them, and supplying the plant with carbon for its structure, is an absolute impossibility.

With a glance at one other class of experiments which bear on this point I have done. I do not know that Sachs has relied on it, but other physiologists have. It has been maintained that not only carbonic acid, but nitrogen free and uncombined, is taken up by the plant through its leaves, and it is plain that if the one can be so taken up there seems no very good reason why the other should not also—possibly not so readily, but still taken up. Both are constituent gaseous elements found in the plant, and if it could obtain one of them through the leaves, it should follow that it might equally have obtained the other also. Now with nitrogen the question has been fairly tried by many first-rate chemists and physiologists, and a great multitude of experiments have been made, and although discrepancies have occurred on points which do not concern this question, I think I may say that, with one exception (De Villa), the conclusion has been unanimous in the negative. It would be tedious to mention all the experimenters, but when I name Boussingault as commencing the inquiry and Lawes and Gilbert terminating it, no question as to the efficiency of the inquiry can arise. Mr. Lawes' concluding words were: "In view of the evidence afforded of the non-assimilation of free nitrogen by plants under the wide range of circumstances provided in the experiments, it is desirable that the several actual or possible sources of combined nitrogen to plants should be more fully investigated both quantitatively and qualitatively."

In conclusion, I trust that others will repeat my experiments and weigh my arguments. It is a very self-confident thing for a man to set himself up in opposition to views entertained by all the *heroes scientific* of his own time, and although I own that I am not generally much troubled by reverence for authority, I still feel that I shall not be sure whether I have been wise or impudent in writing this paper until I have my experiments repeated and confirmed by independent workers. *Andrew Murray.*

GLEANINGS FROM THE ROSE SHOWS.

ROSE shows may be looked at from different points of view, but for the amateur they ought to be something more than mere attractive spectacles. They ought to afford him—as they do if properly studied—valuable lessons in the knowledge of his favourite pursuit, the more so as every exhibition has its distinct features, some of which the writer will endeavour to extract from the great shows that have recently taken place.

After the indifferent display at the Crystal Palace, and the discomfort of crowding and defective light at St. James' Hall, it is refreshing to call to mind the Rose show at the Alexandra Palace—unquestionably the Rose show of the metropolitan season. At this charming place of resort the arrangements and the space are such that, notwithstanding crowds of spectators, every one has ample opportunity for criticising the boxes in detail without a compulsory circulation being enforced by attendant police.

Considering the drawbacks of an unusually trying season, it is surprising in what good order Roses have been presented for public approbation at the great shows that have to this time been held, and the number of amateur exhibitors that have come forward.

The new Roses, particularly English seedlings, have been shown in unusual abundance, and of a quality that promises to render us shortly independent of foreign raisers altogether, except in the case of some extraordinary novelty. This view is strengthened by the general lack of quality in the new French for the current season—partly to be accounted for, perhaps, from the fact that neither Lacharme nor Guillot fils have contributed to the batch. Madame Sophie Propot, Mdlle. Emma All, Marie Louise Peralt (seedling from Baroness Rothschild), Mons. Gabriel Fournier—prize Roses in their own country—are the best we have seen. Turning to the past season's Roses, Duchesse de Vallombrosa, a fine light-coloured flower, somewhat like Bennett's Duchess of Edinburgh or Madame H. Jamain, and La Rosière, a rich dark rose, in the line of Prince C. de Rohan or Mons. Boncenne—both of which, by the way, were finely shown—provided this should ultimately turn out vigorous and hardy it will prove a real acquisition; at present its appearance is in its favour. Baron Bonstettin, another of the dark line, has been generally exhibited in fine condition, so also has Baron Bonstettin; Firebrand, in a different style, and Lord Macaulay, have sustained their repute. The latter is a good companion to Madame Victor Verdier, one of the best Roses for general work we have. Monsieur Alexis Lepère, Comtesse Vally de Serenye, Avocat Duvivier, Madame Ferdioand Jamin, Madame Prosper Langier, Marguerite Brassac, and Monseigneur Fournier, were sufficiently well shown to deserve consideration as highly-promising novelties. Alluding more particularly to English-raised Roses which have filled prominent positions at the shows, and which can be recommended as thrifty kinds for the use of amateurs, the following stand out as the pick of the "tables":—Star of Waltham, Princess Beatrice, and Magna Charta (William Paul & Son); Miss Hassard, Oxonian, and Mrs. Baker (Mr. C. Turner). We may note in this place, that from the mode of introducing seedlings practised here it is much longer before they pass out of the category of new Roses. They are shown at societies, often receiving certificates, but it is seldom that they reach the general Rose-growing public till two or three seasons have passed by. Cranston's Sir Garnet Wolseley has been well certificated, and may prove to be a Rose for everybody; this is a matter for time to decide. Sports seldom are worth much; for example, Bessie Johnson is not equal to Abel Grand, and Letty Coles, in our estimation at least, seems but a dull and dirty paraphrase, with nothing particular to recommend it, of Madame Willermoz.

It is always pleasant to meet old friends and favourites, even in Rose-boxes, especially when they appear in such excellent form as "Jules;" Général Jacqueminot, Madame Vidot, better as shown than most new tinted whites; Chabriland, which, in spite of its exquisite symmetry, appears to be yielding from want of size to such ragged Pæony-like flowers as Paul Néron, the ragged-edged Captain Christy, and the like; Malmaison, unique in its beauty as ever, for it has never given a seedling to continue its strain; and Gloire de Dijon, the amateur's Rose, good for all

purposes. To this last must now be added La France, equally versatile and equally desirable; indeed, with the Gloire la France, the old General, and Malmaison, even the suburbanite may enjoy a feast of Roses of the highest quality, provided they are dwarfs (not on the Brier), and receive the necessary care and proper soil. Both of these remarkable Roses are hybrids of uncertain parentage, forming distinct points of departure for new lines of seedlings. The Gloire has already proved very prolific in this direction. Whether La France will be equally so remains to be seen.

Marie Cointet (might this not be described as an improved Anna de Diesbach?) did not come up to the form Mr. Bennett showed it in at the Crystal Palace three or four years ago. That gentleman has been kind enough—led by my remarks in the Rose number of the *Gardeners' Chronicle*, I suppose—to forward me four blooms, on stout foot-stalks, better than any I noted at the shows. My opinion, nevertheless, still is that it is not an exhibitor's Rose.

Flat Roses of the Baronne Prevost type do not appear to find equal favour in the eyes of modern rosarians with the deeper petalled yet less double varieties. There are a good many fine flowers too of the style—for instance, Triomphe de France, as shown, and with somewhat larger petals, and fewer of them; also Madame Charles Wood. I do not know whether it has been generally noticed by the bulk of rosarians, but with Victor Verdier came in a new and distinct style of wood—smooth, firm, and almost without spines, the foliage being large, leathery, and of great substance. Very many of the highest class modern Roses partake more or less of these characteristics.

The singular and often erroneous nomenclature on the tallies is an ordinary feature at most Rose shows, and suggests the importance of some alteration. Written tallies ought not to be allowed in competition boxes at all. Nothing, except displaying the names of the exhibitor openly, would be a greater guide to partial decisions were the judges disposed to unfair practices. Besides, the tallies ought always to be printed, if only for legibility. Another point not sufficiently attended to is correctness in the tallies. At the Crystal Palace show last year the writer noticed in a prize seventy-two Madame H. Jamain put to Hippolyte Jamain, and *vice versa*. To say the least this denoted carelessness, if not ignorance, on the part of both judges and exhibitors. The stand ought to have been put down.

The fact must have struck close observers, that we have far too many Roses virtually alike—as far as the flowers are concerned; indeed, the lists want weeding out. Some twenty representative Roses might well be taken as types. Some three or four of the best in each might be selected and the remainder left to drop out. Roseries would be the better for such excision, nurserymen would be saved much trouble and sometimes undeserved odium, and we should have a means of forming a tolerable idea of novelties by referring them to types. The writer hopes to be able to present an instalment towards the task before the season has gone by. Space requires further "gleanings" to be deferred to a future date. *W. D. Prior.*

THE COLORADO SPRUCES.

THE three Spruces of the Rocky Mountains, Douglas', Menzies', and Engelmann's, botanically known as *Abies Douglasii*, *A. Menziesii*, and *A. Engelmanni*, seem destined to take such an important position as ornamental trees in the Northern portions of the United States and Europe, that some account of them at the present time will be interesting, and will, I hope, help to make them better known to nurserymen and planters generally. *Abies Douglasii* and *A. Menziesii* have been in cultivation for half a century, having been introduced into England from seed collected in California and Oregon, by David Douglas, a celebrated Scotch botanical traveller, whose labours and untimely death in the pursuit of his profession, the Douglas Spruce will always recall to botanists and lovers of coniferous trees. Although these two trees grew well, and soon became popular in England, all efforts to introduce them into our extreme Northern States failed, or practically failed, as after a few years, more or less, some unusually severe winter had killed all that had been planted, and it seemed settled that our plantations must

be made without reference to these really fine trees. But in 1862 Dr. C. C. Parry, to whose indefatigable journeyings and researches are due the solution of so many of the botanical problems of the Western Territories, visited the Rocky Mountains of Colorado, and sent from there seeds of these two trees to the Botanic Garden of Harvard University. From this seed a large number of plants were raised, which, with a view of testing their hardiness, have been widely distributed through several of the Northern States, where they have stood the trial of the last dozen years, and many of them, too, very trying years to plant-life, without, so far as I have heard, a single one, whether planted on the most exposed situations of the New England coast, or in heavy clay soils in Pennsylvania, having been injured in the slightest degree. As a plant is generally more susceptible to injury from cold or drouth during the early years of its life, and as our plants have passed through these first years so successfully, their perfect hardiness and adaptability to the soil and climate of the Eastern States must, I think, now be conceded.

But why, it will be asked, are these Colorado trees hardy, when the same species had, up to a dozen years ago, proved so unsuited to our climate? The reason for this apparent anomaly is obvious, if we take into consideration the fact that individuals of the same species vary to a remarkable degree in their power to adapt themselves to various conditions of temperature, and that the power of an individual to withstand cold increases in proportion to the distance at which its seed-bearing parent is situated, either from the equator, or above the sea level. Or, in other words, our two Spruces are perfectly hardy in New England, the seeds from which they were raised having been collected at an elevation of some 8000 feet, while plants of the same species, raised from seed collected at comparatively low elevations near the Pacific coast, have almost without exception proved too tender for this climate. The Douglas Spruce, which botanically is closely allied to the Hemlock of the Eastern States, and which, though coarser and less graceful, it somewhat resembles, extends through California and Oregon, as far north as Sitka, and in the Rocky Mountains from New Mexico northward, growing to an enormous size on the Pacific coast, where, in favourable situations, it often attains a height of from 200 to 300 feet, with a diameter of trunk of from 10 to 15 feet. In the Rocky Mountains, however, its average height is hardly above 80 feet, and its growth there is slower and less productive of valuable timber. But it is as an ornamental, and not as a timber tree, that we are now considering this species. As such, few coniferous trees surpass or even equal it, for it has thus far retained in cultivation (and some of the first trees planted in England are now over 100 feet high) its lower branches, and close, dense pyramidal habit; and in this it contrasts most favourably with such trees as the Norway Spruce and many of the Spruces and Silver Firs of the Old and New World, which, however beautiful and thrifty in their young state, become either naked and unsightly skeletons, or destitute of lower branches, long before they have reached half their full development. For this reason the Douglas Spruce should be selected in preference to any other of which, in cultivation, I have any adequate knowledge, where it is desirable to plant a tree of pyramidal habit, which not only is beautiful in its young state, but which will improve for generations.

The second of our species, *Abies Menziesii*, in favourable situations attains a height of 100 feet, and has nearly the same geographical range in North America as *Abies Douglasii*. It also, under various names, extends through Kamtschatka and the Amoor country to Japan. In the Rocky mountains this tree is found at an elevation of from 6000 to 9000 feet, and never forming extensive forests, as do many coniferous trees, but scattered widely here and there, and always in low, wet situations, generally along streams at the water's edge, where its roots are constantly kept cool and moist by the mountain torrents. This natural selection of a cool, moist soil, indicates under what conditions this tree can be most successfully cultivated. According to Dr. Parry, *Abies Menziesii* is, in the Rocky Mountains, a tree of rather an oval outline, pointing upwards with a rapidly tapering trunk. It has a thick grey rough bark, and its leaves are remarkably broad, stout, and very sharp pointed; indeed, so harsh are they that it is painful to grasp one of the

branchlets with the naked hand, and by this peculiarity the species can be most readily distinguished, while young, from several other Spruces, which, in their early years, have certain points of resemblance.

The young plants, although of rapid growth, are remarkably compact and beautiful, especially those of them (about 20 per cent. in our seedlings) which are of a bright bluish grey tint. In fact, these young "Blue Spruces," as cultivators are beginning to call them, are the most beautiful and valuable hardy Conifers for this climate I know. Still, it is only in its young state, probably, that this species will make a desirable ornamental tree, as it has been observed that, when growing naturally, the bluish tint disappears from trees over 30 feet high, while, long before its full development is reached, loose, unsightly branches, nearly destitute of foliage,

manni resembles the Black Spruce of Eastern America, for which it was mistaken by all botanical travellers in the Rocky Mountains, until Dr. Parry detected its specific distinctions, and dedicated it to the distinguished botanist whose name it bears. Of its merits as an ornamental tree I cannot as yet speak with so much confidence as of the two trees already mentioned, as material for a satisfactory trial has not been available. But, probably, its resemblance to one of the common trees of the East will work against its general popularity, while its alpine character, and consequent habit of starting to grow in very early spring, will render it unfit for cultivation, save in the extreme Northern States. In St. Petersburg, as I am informed on the best authority, Abies Engelmanni succeeds perfectly, in spite of the extreme cold of the Russian winters, and, as heretofore, the only Conifers

of their retaining vitality for but a very short period, they were all sown the day after arrival, and, though not contained in pans, covered a space of over 300 square feet, closely packed together. About 33 per cent. germinated, some as early as the fourth day after sowing, and many in a few days reached a height of 18 inches.

Upwards of 1900 plants were transmitted, August 12, in thirty-eight Wardian cases made specially to accommodate the rapid growth of the seedlings, to Ceylon, under charge of a gardener. Of the whole consignment 90 per cent. of the plants reached Dr. Thwaites in excellent condition, and they will remain in Ceylon for the present under an arrangement which I suggested between the Indian and Colonial offices—that the young plants which could not thrive in the climate of Calcutta or any of the

FIG 14.—CLIVEDEN, THE RESIDENCE OF HIS GRACE THE DUKE OF WESTMINSTER. (SEE P. 69.)

take the place of its early compact habit. This comparatively early fading of beauty is less objectionable, perhaps, in an ornamental tree in this country, than in almost any other, and is quite compensated for, in this case, by the superlative beauty which graces its early years. As a hedge plant for this climate *Abies Menziesii* presents qualities possessed by no other plant, and when it becomes, as it should before long, as common and cheap in our nurseries as the Norway Spruce, it will be used for this purpose in preference to that, or any other evergreen.

Abies Engelmanni, the third of the Colorado Spruces, is the most alpine in character, forming in the southern Rocky Mountains vast forests above 8000, and reaching even 11,500 feet above the sea level. This tree forms a shapely, tapering spire, from 60 to 80 feet high, with a trunk slender for its height, and which is covered with a thin, scaly, reddish-grey bark. In general appearance *A. Engel-*

manni available for planting in northern Russia have been the Scotch Pine and the Siberian Spruce, its general introduction there is considered of the greatest value and importance. By far the most valuable of the Colorado Spruces, as a timber tree, and the equal in this respect to the Black Spruce, it is not improbable that *Engelmann's Spruce* will some day form an important element in the formation of artificial forests in Northern Europe. *C. S. Sargent, in the "American Agriculturist."*

THE ROYAL GARDENS, KEW.

(Continued from p. 44.)

INDIARUBBER.—On June 14 of last year Mr. H. A. Wickham, a resident on the Amazons, who had been commissioned by the India Office to collect seeds of the *Hevea brasiliensis*, arrived in England with 70,000, obtained on the Rio Tapajos. In consequence

more accessible gardens of continental India, should be nursed and established in Ceylon for subsequent transmission through the Indian gardens to Assam, Burmah, and other hot, damp provinces of India proper. I am happy to say that the plants are thriving under the management of Dr. Thwaites, who has obtained the authority of his Government to establish a supplementary tropical garden at a lower elevation than Peradeniya (1700 feet) for the more rapid multiplication of the *Hevea*, *Castilleja*, *Chocolate*, and other plants that require a maximum of heat and moisture.

In addition to the principal consignment to Kew small parcels of *Hevea* plants were sent to the following places:—Africa (West Coast), Burmah, Dominica, Jamaica, Java, Queensland, Singapore, and Trinidad. In the case of Singapore the result was unfortunate. Owing to the delay on the part of the India Office in paying the freight, the cases did not come into the hands of the Superintendent of the Botanic Gardens,

to whom they should have been consigned, till the plants were nearly all dead.

A plant in cultivation in the Botanic Gardens of Regent's Park, London, of Buitenzorg (Java) and Mauritius, under the name of *Hevea guyanensis*, proves from specimens transmitted to Kew by Mr. Horne to be entirely different, and is a species of Manihot, apparently *M. Glaziovii*, Muell. Arg., which is said to come from Rio Janeiro.

On November 21 Mr. Robert Cross, who, in addition to the commission given to Mr. Wickham, had been sent to South America to bring home live plants in the event of its proving impossible to transmit alive to this country the very perishable seeds, reached Kew with about one thousand living young *Hevea* plants. The most promising of these have been retained at Kew during the winter, and a portion

thousand one hundred tons annually. The botanical nature of the plant is at present uncertain, but it may possibly prove identical with *Manihot Glaziovii* already mentioned. It is at any rate perfectly different from *Hevea* and *Castilloa* in character, habit, and habitat. It grows in a climate with a marked dry season, amongst a scrubby vegetation, and has stout short branches and deciduous leaves. Forty-one of the imported stems have grown, and as many young plants have been obtained from these by cuttings. The seeds were raised with difficulty during the winter, owing to the seedlings damping off soon after germination—a characteristic of plants of similar habit from similar climates; fourteen plants, however, are growing from this source.

(To be continued.)

situated, there it must remain since it cannot be removed. Where existing evils cannot be cured, the next best thing to do is to prevent others from occurring, and this, as applicable to the subject in hand, can only be done by attention, care, and vigilance on the part of the planter in all future operations. The style and selection of the mansion, formation of the ground, exposure, quality, and condition of soil, and many other things have to be duly considered in selecting and disposing of trees for ornamental and pleasing effect. The following are a few of the many points for consideration which the planter may do well to consider in laying off the woodlands of an extensive and splendid domain.

Now is the time when the effects of trees on the landscape should be considered, for I see no good reason why the uncertain flicker of an autumn day

FIG. 15.—THE FLOWER GARDEN AT CLIVEDEN, AS SEEN FROM THE TERRACE FRONT. (SEE P. 69.)

will be sent to India as soon as the state of the weather permits.

The stock of *Castilloa elastica*, brought last year to Kew by Mr. Cross, has been propagated as rapidly as possible, and plants have already been distributed to Africa (West Coast), Ceylon, and Java. Dr. Thwaites reports that of thirty-one plants transmitted to him twenty-eight have arrived in perfect health, and have thriven vigorously.

A plant to which I alluded in my last report, and which is to be found in some Continental and English gardens under the name of *Castilloa elastica*, proves under cultivation at Kew (although possibly a species of *Castilloa*) to be certainly distinct from that plant both in the form of the leaves and in the habit.

Along with the *Heveas* Mr. Cross brought seeds and plants of an undescribed Rubber tree, which furnishes the "Ceará scrap" of the English market. The export of this has been reckoned at one

Forestry.

THE distribution and appropriation of trees to their right and proper locality is a subject of forestry well worthy of more attention than it has hitherto received. The natural pleasure and delight which trees afford to all who have any measure of capacity for enjoying them is so great, that criticism is seldom indulged in regarding their inappropriateness and unsuitability for any situation, however ineligible. The Willow tree on the smooth carpet-like lawn, the Birch in cultivated fields, the Scots Pine in the rich Clover park, or black Italian Poplar on a dry arid peak, are all, to adopt the common phrase, "the right trees in the wrong places." A stately or graceful tree is of itself an object so attractive and charming that the situation on which it stands, its own special characteristics and surrounding associations are all lost sight of, at least when considered in connection with the established fact that, whether rightly or wrongly

should be so highly esteemed above that of several weeks of steady glowing beauty. A few degrees of frost, a shower of rain, a gale of wind, or humid atmosphere for a few days, are each a common but sufficient influence to blast and dissipate all our prospects, joys, and pleasures of the autumn landscape. Not that we should delight and enjoy autumn less, but that we should enjoy summer more, is the sentiment I would like to express regarding them.

1. Such trees only should be planted in proximity to the mansion as are well known to survive to a great age, and maintain during their existence health, vigour, magnificence, and splendour in the highest possible degree. Foremost of those trees combining such qualities are the Oak, Spanish Chestnut, Sycamore, Lime, Horse Chestnut, Elm, Beech, and Ash. These are for the lowly foreground, but only for situations where the soil is good and other influences favourable.

2. For an extreme upland district, where the soil is inferior and exposure severe, the landscape trees may consist of the common Scots Pine, Birch, and wild or Aspen Poplar, together with the Gean tree and Mountain Ash, distributed or combined, to suit the general surroundings of the locality and conformation of the ground.

A very pleasing and impressive effect is produced on entering the pleasure grounds of a noble mansion by passing through the following groups or masses of woodland in the form of belts or zones intersecting the drive. At the entrance gate, which may be of Swiss style, is a large mass of Scots Pine, unbroken or interspersed with any other species of tree. The darker and more cloudy the aspect so much the better, which a single tree of lighter and lovelier hue would entirely destroy. The next zone may be Birch, mixed with the Scots Pine at its margin, but all Birch in the centre.

A zone of Aspen Poplar may next be reached first mixed with Birch at its margin, as the Birch with the Scots Pine, and gradually forming into one entire mass of itself in the centre, and again mixing on the opposite margin with the succeeding mass. A group of Larch on an elevation or sloping bank of good dry soil will also be found pleasing and delightful. A group of Norway Spruce on a level piece of soft or even drained boggy ground will also please the sight.

An eminence may be crowned with the hardy Silver Fir, but the further into the distance the better, as the outline is hard and irregular, partaking more of the picturesque than the beautiful.

Emerging from the denser and larger masses of forest the eye should next fall upon groups of Laburnum, Lime tree, Hawthorn, varieties of the Maple, various weeping subjects, and groups of shrubs and small trees. *C. Y. Michie, Cullen House, Cullen.*

THE COMING BEETLE.

A CROWDED meeting of members of the Entomological Department of the Irish Animal Kingdom was held last night at the "Hole in the Wall," Dublin, to consider the expected arrival from the United States and Canada of the Colorado beetle (*Doryphora decemlineata*). The assembly chiefly consisted of the Coleoptera, but representatives of the Aphaniptera, Hemiptera, Diptera, Homoptera, and Orthoptera were also present. The chair was taken by—

The Stag Beetle (*Lucanus cervus*), who, in a few words, stated that the advent to this down-trodden island of the Colorado or Potato beetle, already found on the Continent of Europe, was now merely a matter of time. He should, for his own part, receive him as a brother—with open horns.

The Rosechafer (*Cetonia aurata*) was of opinion that they should prepare to give the distinguished immigrant a warm reception.

The Bleeding-nose Beetle (*Timarcha hevigata*) said that had been done by the people at Cologne, where they had covered a field in which their American cousin had been detected with sawdust and petroleum, and set it on fire. ("Shame!") But, for all that, the Colorado beetle "had been seen on the wing," and, please the Potatos or not, would soon be among them. ("Hear!")

The Cockchafer (*Melolontha vulgaris*) was a beetle to whom nothing came amiss. In his larva state he, like the *Doryphora decemlineata* and the Irish population, rejoiced in Potatos. But the world was quite wide enough for both him and the Potato beetle. They had both the same interests, and the same enemies. Man would be down on the Potato beetle's larvæ with poison. Boy would be down upon him, too, with foot and finger. He would probably have to beware of the Goatsucker, or Nightjar (*Caprimulgus europæus*), and also of the Kestrel (*Falco tinnunculus*); but the former was only a bird of passage, and gamekeepers were fast exterminating the latter, which fed chiefly on mice and insects, by shooting it down. ("Hear! hear!") It was a particular foe of his kind, and he hated it, as he did the whole brood of Saxon destroyers, of which this was one of the worst. (Cheers.)

The Devil's Coach-horse (*Staphylinus (Oxyopus) olens*) supposed that himself and the Potato beetle would perhaps be considered to belong to the same stud. But he, the D. C., was a carnivorous beetle, and feared he hardly deserved his name; for, what-

ever he looked like, as he consumed carrion and ate destructive insects, he did mankind service, though he cocked his tail at them, but at none so high as the base, bloody, and stupid Saxon.

The Shard-born Beetle (*Gastrotripes stercorarius*) made an observation inaudible on account of his drowsy hum.

The Turnip Flea (*Haltica nemorum*) hoped their Colorado friend would do for Potatos as he, the Turnip Flea, did for Turnips and Swedes, but that care would be taken that the value of the crops destroyed should be deducted from the rent, so that the loss might fall on the landlords.

The Domestic Flea (*Pulex irritans*) would hail the arrival of another annoyance to the human race—he meant, of course, the Saxon oppressor.

The Norfolk Howard (*Cimex lectularius*) cordially cried "ditto" to the last speaker.

The Plant Fly (*Aphis vastator*) could, as his technical name might seem to imply, help to devastate 'taters, but he could not destroy everything off the face of the earth, even with the aid of the most patriotic motives. He expected to find the Colorado beetle an efficient ally.

The Meat Fly (*Musca vomitoria*) had to do chiefly with meat. He should be glad to see a new-comer attack Potatos; and as for gardeners and farmers or St. Patrick himself trying to stamp him out in this favoured island—they be blown!

The Praying Mantis (*Mantis religiosa*) was not himself a vegetable feeder. Yet he sympathised with their Potato brother. He did not look upon him in the light of an enemy to man. No; he regarded him rather as a beneficent dispensation—a bountiful provision for the limitation, if not the extirpation, of a tuber possibly working, unsuspected, evil amongst men. Who knew? The Potato beetle might have been sent to supplement the Potato famine, and still further reduce the population of this beautiful but mis-ruled island. If so, he would still prove a friend to the national cause, as the Potato famine had done, for he saw in that the great spring of migration to the United States, and the tap-root of Fenianism. To all the words of welcome with which the approaching advent of the *Doryphora decemlineata* had been hailed by preceding speakers he devoutly responded "Amen!"

Great excitement was here produced in the meeting by the announcement, on the best authority, that a large specimen of the Potato beetle had just been caught climbing up a rope to Dublin quay.

The Domestic Flea—who was proud to avow himself a Home-Ruler—begged to move three cheers for the invader. Any invader of his unhappy country was welcome, and the worse the better.

Three cheers for the Potato beetle were then proposed from the chair, and given with tremendous buzzing.

The cheers had hardly subsided when a pair of devil's coach-horses was rapidly driven up, bearing the following telegram:—

"House of Commons, Thursday, Midnight.

"Hiels Beach says it isn't a Colorado beetle that's in it, but a stone beetle, twice as big and not a bit like the raal ould Colorado boy. Don't believe it. The Saxons want to stand between Ould Ireland and prececdency in possession of the genuine Potato bug. I'm holding up for the raal ould Colorado. Hurroo!"

The reading of this telegram was the signal for a scene of unprecedented excitement, amidst which our reporter, being recognised, was expelled with circumstances of the utmost ignominy. *Punch.*

Apiary.

STRAW HIVES.—So far this season my bees have not been as successful as in previous years. Good swarms have been far from plentiful, although, judging from my own apiary, they have gleaned a fair harvest of honey. I thought I would make a few notes, as well as general observations, during the present season as to which were the most profitable taken from a cottagers' standpoint, the common hive or the Woodbury hive being the two chiefly observed. We have now in use in our farm apiaries many of the very large straw hives, which hold about as much as three of the ordinary hives. I need scarcely say they are found to be a complete failure. A practical bee-keeper told me only very recently that one of these monster skeps on his stand had not swarmed for three years. "Well," I replied, "you have probably taken from

it several large supers." "Nay," said he, "it has stood as now—untouched."

The reason of their not swarming is easily explained. The bees constantly dying off during the working season leave the population at a standstill. Thus the hives are never crowded, and the bees are not, under these easy circumstances, compelled to seek a new home; neither would it be wise to super such a hive. Hives about 12 inches square are the most profitable, especially for cottagers. I do not recommend bell-shaped hives, except to those bee-keepers who are always averse to meddling with them and never interfere with their stocks from the day in which they are hived to the time when they are cruelly slaughtered over brimstone fumes; to these people, who can never believe in anything except what their forefathers used two centuries since, I say anything will do, and by all means adhere to the common bell-shaped hive, which is sold by every ironmonger. On the contrary, to the cottager who takes a deep interest in the welfare of his colonies, I always advise the use of the flat-top hives, generally called Payne's hive.

We first noticed two common hives placed on the same stand with two excellent Woodbury hives. At the beginning of the season the latter were considerably stronger, and appeared to promise the best results; the straw hives were not interfered with. Mark the results in this single apiary: up to July 10 we have had six swarms from the straw hives, with every prospect as well of a fair yield of honey from the old stocks and first swarms, but the Woodburys have neither swarmed nor gathered any extra store in the supers; they appear to be stationery.

In a neighbour's garden we find nearly the same results. To test whether a straw or wood hive (as near the same internal measurement as it was possible to make them) was the most useful—we observe the wood hive sent out a small swarm, scarcely worth the trouble of hiving, whilst the straw skep sent out two swarms, one so early in May that it has swarmed again—thus two swarms and a virgin swarm, so that we have four stocks inclusive of the parent stock.

We have observed for many years that a poor woman whose chief talk is, whenever we get upon the bee topic, that she never received one penny from the parish, but she evidently obtains a better living from her bee garden, for the last year she had, we believe, an average the season through of forty-three stocks. We have often tried to persuade our friend to use wooden boxes instead of her favourite straw skeps, but in vain, on the plea that they would be more durable, she will not use them. Our friend's hives are often exposed fully to the weather, yet they always appear to do well, and when every one complains of the bad honey harvest she can secure a fair yield, for last year she obtained from honey and wax alone £39, besides the few extra pounds secured by the sale of new swarms. Old Betty attributes all her success to the old-fashioned hive, for she knows nothing of supering, though we have now taught her how to drive her stocks—instead of destroying them, and afterwards placing two condemned stocks in each empty skep, to feed them up liberally; these often make good stocks. We hope again shortly to return to this subject. *R.*

Florists' Flowers.

DOUBLE PYRETHRUMS.—The progress being made with the double Pyrethrum is seen in some splendid flowers sent by Messrs. Kelway & Son, nurserymen, Langport, for inspection. They are remarkable for their great size, fulness, symmetry, and fine and striking hues of colour. The Pyrethrum, both single and double, are most effective border flowers, and while it is not always a gain in point of beauty or attractiveness to change the single character of the flowers to be double, it yet seems to be a decided advance in the case of the Pyrethrum. The habit of growth of the double varieties is also of a more compact character generally than that of the single varieties, which is a gain.

Of the varieties raised by Messrs. Kelway & Son the following are well worthy notice:—Amethyst, pink fleshed with violet blue, large, full, very fine and striking in appearance; Achilles, rosy pink, large, full and very fine; Captain Boynton, cherry-red, a fine dash of colour, large and full; Captain Nares, soft magenta, fine shape, and remarkably full; Ceres, bright pink, deepening to rose on the ray petals, large and very fine; Cleopatra, pure white, large and

full; Duchess of Edinburgh, pale pink, tinted violet, and surfaced with silver, very pretty and attractive; Galopin, deep magenta shaded with maroon, very fine in colour, large and full; Kreimhilda, pale pink, a pretty hue of colour, large and full; and Queen Mary, blush flushed with pink, fine and full.

The exhibition of the Royal Horticultural Society on June 19 included among many things of peculiar interest some remarkably fine blooms of double Pyrethrum shown Mr. H. Hooper, Widcombe Hill Nursery, Bath. They were so attractive, and of such rare excellence, that they asserted their claim to be included in the schedules of prizes of horticultural societies. They nearly rival the quilled Asters, the only exception being that they do not exhibit the shades of purple, blue and violet found in the latter; but these will come in course of time. As a decorative hardy border flower at this season of the year, the Pyrethrum claims, and should receive, the fullest public attention. *R. D.*

Garden Operations.

PLANT HOUSES.

GREENHOUSE HARD-WOODED PLANTS.—All specimens and half specimen greenhouse hard-wooded plants that it is necessary to expose for a time in the open air with a view to thereby ripen their wood, so as to insure their flowering freely and to harden up the foliage sufficiently to enable it to resist the attacks of mildew through the damp autumn months, should now be stood out. It is not advisable to expose them to the full influence of the mid-day sun for a few days at first, as the change from even the best constructed light houses to the unobstructed force of the sun's rays is very great, and will sometimes not only disfigure the leaves, but permanently injure them; for this reason the plants should be stood for a short time at the north side of a wall or trees. Protection ought to be given to the pots so as to keep the sun from coming directly upon them; stand them on a bed of ashes sufficiently thick to exclude worms, if the bed is kept damp the moisture arising from it will benefit the plants in hot sunny weather, and will also tend to keep down red-spider, to further secure which all plants that are liable to it should be daily syringed, wetting the under-side of the leaves. Some of the finest rooted and most tender subjects should not be stood out in this way. Amongst such as are better kept under glass all the year may be enumerated *Dracophyllum gracile*, *Leschenaultia biloba*, *Gompholobium*, *Daphne indica*, *Tetratheca verticillata*, *Pimelea hispida*, and *Roella ciliata*. With these there is nothing gained by exposure, neither is it well to put out small young stock, as the drying influence of sun and air on the small body of soil in which the roots are contained often has the effect of producing a hard stunted state which is difficult to get them out of; and when these have been grown through the season in a good light pit or house, from the thinner, more open condition of their shoots than in the case of larger plants, the influence of light will better have solidified the growth as it has progressed.

There are few more useful decorative plants than Nerium (Oleander) splendens, both the pink and white varieties. Why they are not more generally used it is difficult to imagine, as there is scarcely a property essential to a popular plant that they do not possess. They are of the easiest possible culture, being capable of bearing an amount of neglect and indifferent usage that would be fatal to nine-tenths of the plants we cultivate. The flowers are extremely beautiful, and adapted for decorative purposes on the plant or in a cut state. With a little warmth they can be brought into bloom early in the season, and if sufficient are grown a portion will come in by ordinary greenhouse treatment during the later summer months when indoor flowers begin to be scarce. For a roomy conservatory, if desirable, they may be grown to a large size, or they will flower well in a 6-inch pot. To bloom them satisfactorily there is one essential, the wood must be thoroughly ripened; in no way can this be accomplished with so much certainty as by standing them out-of-doors under the influence of full sun in the warmest position that can be found, where the growth will get thoroughly hardened, to further assist which give no more water than is necessary to prevent the young shoots flagging; this will tend to stop any further extension. The plants should be turned out at the present time, and allowed to remain until the beginning of September. In the case of large specimens, after being subjected to this ripening process, the shoots may be taken off with some four or five joints to each, and struck singly in small pots; if a little bottom-heat can be given them without much increase of the temperature overhead, they will root in a few weeks without top growth being excited, after which they be moved into 6-inch pots, and so kept through the winter.

Solanums planted out-of-doors in the spring ought, when the weather is dry, to receive enough water to keep them in a healthy growing condition, and should occasionally be examined to see that they are free from red-spider, for although much less susceptible of its attacks planted out than when grown in pots, yet it sometimes makes its appearance, and if not destroyed seriously injures the leaves. A good syringing with Gishurst, at 2 oz. to the gallon, carefully applied so as to reach the whole surface of the leaves, will generally be found effectual. When they are grown in pots and are affected with this insect the best plan is to dip them; they require unremitting attention with water when their roots are thus confined, and should have liquid stimulants once a week, or the foliage is almost certain to have a yellow, sickly hue.

SOFT-WOODED PLANTS.—Mignonette sown early in the season for flowering in pots must not be allowed to suffer for want of root-room, the size of the pots used should be proportionate to the strength of the plants and the size they are intended to grow to. This plant ought to have good soil well enriched with rotten manure and a little leaf-mould. Keep the flowers picked off as they are formed, and the plants tied into the required shape. Mignonette looks much better when trained to a more natural form than the stiff, objectionable pointed cones frequently seen; the plants should stand where they will have plenty of light and abundance of air, otherwise they will become weak and drawn—a condition that, if once they get into it, cannot afterwards be remedied: they must never be allowed to suffer for want of water, or it induces a yellow appearance of the foliage. A little more seed should now be sown in 48-sized pots to bloom in the spring, standing them out on a bed of ashes in a frame, with the lights off in all but exceptionally wet weather: when they are well up they should be thinned to three or four plants to each pot, and when some growth has been made move them into others a size larger, in which they will be wintered and ultimately flowered. A little *Calceolaria* seed may be put in: it is well to sow twice at an interval of about three weeks—the second sowing can be had to flower after the others, and in this way will come in very useful. *T. Baines.*

ORCHIDS.—The earliest plants of *Dendrobium nobile* that have made up a good growth, must now be taken from the *Dendrobium*-house where hitherto they have been growing, and if in baskets suspended from the roof of a cooler house, a vinery, Peach-house, or a house of a similar character where plenty of light is obtainable, at the same time where the plants will in some degree be shaded from the direct rays of the sun. As the growths are thus exposed to a greater amount of light and air and a cooler night temperature they will gradually become ripened and matured, and in due season will produce the desired show of flowers. *W. Swan, Fallowfield.*

FRUIT HOUSES.

CUCUMBERS.—Pot off the young plants intended for early winter fruiting as soon as they have made the first rough leaf, and keep them close to the glass, to prevent drawing. When they begin to grow freely the leaders should be supported with sticks, and if the pit is not ready for their reception by the time the pots have become moderately full of roots, a second shift into 8-inch pots may be given. A close pit, where they can be well syringed, with a little bottom-heat from fermenting materials in preference to hot water, will suit them well. Endeavour to maintain a free healthy growth in the fruiting-pits by frequent removal of old bearing vines and foliage, to make room for young fruitful growths, which should be stopped one point beyond the fruit, and by light cropping and liberal supplies of tepid liquid manure. If shading is resorted to, the blinds should be drawn down early on bright mornings until the fruit and foliage is quite dry, but on no account should they be allowed to remain all day, unless the weather is very bright and the plants show signs of flagging. Maintain a bottom-heat of 80°, and close about 4 P.M. with moisture; avoid fire-heat as much as possible unless, as is now often the case, the external temperature falls below 50°. Plants growing in pits or frames will well repay the trouble of turning and renovating the linings, also for covering with mats at night. Water and syringe regularly, not later than 4 P.M. Dress over twice a week, and use glasses for keeping the fruit clean and straight. *W. Coleman.*

ORCHARD HOUSE.—When the early kinds of Peaches of recent introduction are grown in pots the most forward should now have full exposure to sun and light by turning the leaves off the apex of the fruit and pinching out the points of the shoots to improve the colour, size, and flavour. Later kinds now swelling their fruit should be supplied with abundance of weak liquid manure, and in some cases a renewal of the surface dressing may be found necessary when trees in small pots are carrying heavy crops of fruit, particularly if the roots have not found their way into the borders on which they are placed.

Maintain a moist growing atmosphere by syringing freely, and closing the ventilators about 4 o'clock on fine afternoons. Open the house early the following morning, stop all strong shoots, and shorten back where too much crowded for the well-being of the fruit. Figs in pots will require liberal supplies of water while the fruit is swelling, also good syringing to keep the foliage free from red-spider until such time as the fruit shows signs of ripening, when it must be discontinued, but careful watering must be followed up, as any sudden check would end in the dropping of the fruit. Plums now ripe, or ripening, may be placed together at the coolest end of the house, or they may occupy a cool, airy structure with the Cherries, where they can be protected from wet and birds. Although I do not recommend Grapes to be grown in the orchard-house either in pots or otherwise, where their culture is attempted, early kinds will be best adapted for the purpose, and these should be trained as single rods over the paths where they are least likely to be affected by the free use of the syringe amongst the other occupants. Hamburgs, Muscadines, and Sweetwaters, if thinned early, and well stopped and attended, sometimes give good fruit, but their culture in a separate compartment is always attended with the best results. Cherries from which the fruit has been gathered will derive great benefit from frequent syringings to cleanse the foliage from all insects which may have gained a footing during the time the fruit was hanging. If placed on, or partly plunged in, a bed of ashes in a light, airy, but sheltered situation, the young spurs will get well ripened for next year's fruiting. *W. Coleman.*

KITCHEN GARDEN.

Now is the best time to get in the main sowing of Endive of sorts for the main supply for late autumn and winter salading. Some improved varieties of the Batavian section have been introduced of late years, and are so valuable as possessing characteristics of hardness during winter that they should never be omitted. For early autumn purposes the moss-curl varieties are generally the first to come into use, which are succeeded by the old broad-leaved Batavian, and these again by Fraser's Improved Broad-leaved, and the new Batavian Improved Round-leaved, which is a very desirable sort, and blanches well. The Digswell Prize is a good green curled variety. Now also is a good time to commence the sowing of Lettuces for early autumn and on to early winter supply; indeed, on this and the next sowing will depend the principal supply for storing purposes for the winter, for which they should be well grown up to the tying point, and if taken up and tied when thoroughly dry and clean they will blanch and keep longer than such as have been tied a week or so before storing. The same remarks will apply in some measure to Endive, but, as a general rule, that crop may be kept longer out, and in mild winters may be very well blanched fit for use without storing; still, it is always best to secure a good supply of well-advanced plants for storing, in case of the advent of very severe weather. A good breadth of the earliest-sown should be planted out at once, and every encouragement given to maintain a free and constant growth by frequent applications of water and surface-stirring, which will tend to prevent the running to seed which often occurs in the early-sown plants. Now also is a good time to plant more largely of the different varieties of Lettuce from the successional sowings, as those planted after this time will seldom run to seed, and towards the end of next week a good supply of Hicks' Hardy, Hardy Winter, and Bath Brown Cos should be sown to furnish strong plants to stand through the winter. All these crops will require a well manured and good cultivated soil in order to ensure that crispness and delicacy of flavour so highly prized by all true lovers of salad. There can be no enjoyment of a salad of which the main ingredients, as Lettuce or Endive, are withered and flabby like pieces of thin leather, instead of being thick and crisp, and so tender as almost to melt in the mouth. With the advent of some very desirable showers the work of transplanting the various crops for winter and spring supply must be vigorously followed up. Of course all autumn and early winter Broccoli are put out and well started, those to stand through the winter ought also to be planted in their final stations, if not there must be no delay, for if they are not advanced beyond a certain point during the autumn growth it will often happen that they will not produce heads in the spring, but grow on (if left) through the next summer and winter. The planting-out of more trenches with Celery for succession must not be neglected. Those first planted will now be well started into growth, and may be liberally supplied with stimulants, either as drainage from the manure-heap or a solution of guano in water. Cauliflowers, Cabbages, and other members of the Brassica family are often at this season much disfigured by caterpillar. Their advent should be watched for, and hand-picking at once resorted to. There is no better remedy. Dressing with obnoxious liquids is out of the question. *John Cox, Kettering.*

THE
Gardeners' Chronicle.

SATURDAY, JULY 21, 1877.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, July 24 { Worcestershire Horticultural and Agricultural Show at Kidderminster (three days).
WEDNESDAY, July 25 { Roehampton Horticultural Society's Show.
Acton Horticultural Society's Show.
THURSDAY, July 26 { Kendal and District Horticultural Society's Show.

ASSUREDLY there is little room for dogmatism on any point of natural science, and least of all perhaps in the case of vegetable physiology. On these grounds, then, no less than on the fact that anything that comes from Mr. MURRAY's pen is worthy of respect, we call attention to his paper on the FLOW OF THE SAP read before the Scientific Committee on Tuesday last, and which, by permission of the author, we reproduce in another column. Mr. MURRAY has the courage of his convictions, and when he has made up his mind upon a certain point he pursues it to its logical conclusion, fearless of consequences and undismayed at the confusion and wreck that may be created. Now if the premises be correct and sound, this fearless devotion to truth regardless of consequences is naturally one of the very highest qualifications of the true naturalist, and one that every man of science should aim at. But before he proceeds to pull down he should be well assured that every step he has made is secure from assault, and that his position is perfectly impregnable. The most valuable part of Mr. MURRAY's paper is that descriptive of his experiments. He starts with the assumption that there is no such thing as a descent of the sap at all, and, if we correctly interpret his views, that there is no such thing as a descent of the nutrient fluids elaborated, as generally held, in the leaves. To make this assumption a matter of certainty, Mr. MURRAY contrived some experiments in the manner detailed in his paper. To make matters clear without entering into details, which may be found in any textbook, we may say that the old notion of a regular systematic descent of the sap, comparable to the return current of a hot-water apparatus, or to the flow of arterial blood from the heart, has been for some time abandoned or very materially modified. Mr. MURRAY goes a step further, and denies that there is any descent at all.

We refer to the paper itself for an account of the mode of experiment. It must suffice to say that a solution of litmus was introduced into the stem through a wound made for the purpose. The result was that throughout the whole length of one side of the stem, above and below the cut surface, the solution found its way, while not a trace of it could be detected on the opposite unwounded side. Mr. MURRAY's argument is that on the ordinary principles of endosmosis it ought to have been found throughout the stem on the unwounded as on the wounded side. Mr. MURRAY's results may be accepted without hesitation. The experiments were no doubt carefully made and accurately observed—they are of themselves not open to doubt.

But are we justified, on the strength of these experiments in upsetting the whole theory of the nutrition of plants, based as it is on innumerable experiments and observations, in denying the influence of light on the leaves and other green parts of plants? Can we so lightly abandon the belief—Mr. MURRAY says hypothesis—that plants obtain the greater part of their carbon from the carbonic acid of the atmosphere? Can we bring ourselves, on such evidence, to deny "all power of taking anything into the system through the leaves?" Most assuredly

we should show a sad want of scientific caution if we did so.

Suppose Mr. MURRAY's experiments to be faultless and unassailable—suppose that no explanation be forthcoming save that offered by himself—what then? Should we be justified in at once assigning a degree of importance to them greater than that attaching to the hundreds of experiments which tell a different tale, and upon which the present system of vegetable physiology is now based? To our thinking, certainly not. Mr. MURRAY asks too much of us; indeed, like some merchants, he asks more than he means to take, for the concluding paragraph shows a greater sense of the value, and specially the weight, of evidence than other portions do.

To state the case against Mr. MURRAY's views fully and fairly, and to indicate where Mr. MURRAY is in opposition to received opinions and facts, would be to write a treatise on the vegetable physiology of the nineteenth century. Let us see whether some one point or so cannot be taken in illustration of the rest. Let us take leaf-action. We had thought that if there was one fact better established than another in vegetable physiology it was the inhalation of atmospheric air by the leaf and other green parts of plants, the breaking up of the carbonic acid gas therein under the influence of light, the retention of the carbon, and the elimination of the oxygen. Consequent on this, we get starch formed in the leaves by the chlorophyll. This is no theory; it is an accepted fact. It has been seen over and over again. That starch, or starch-producing fluid, must surely descend on occasion like the other nutrient fluids, developed or elaborated in the leaf. If not of what use are they? The leaves can hardly be considered as store-houses—they are factories, and from them are drafted the manufactured products upwards, downwards, sideways, according as circumstances necessitate or requirements dictate.

But we cannot now pursue this matter further. Mr. MURRAY's views would, if accepted, negative all that has been laboriously acquired by chemists and vegetable physiologists from PRIESTLEY downwards. We do not look forward to any such result. Change and progress—the wiping away of many errors, the clearing up of many doubts, we may look forward to, nay, is what we long for in the future, but so radical a revolution as Mr. MURRAY foresees seems to us the height of improbability. Mr. MURRAY has the right to ask us how his results are to be explained, but before we could give an answer satisfactory to him or to ourselves we should require further evidence, and amongst other things as to the tissues through which the fluid passed. Did it pass from cell to cell oozing through the wall of one into the cavity of another, or did it pass through the intercellular spaces laid open by the nick, and by capillary action and gravity press down between the fibres and tubes of the stem? The circumstance that a "nick"—a wound, an exposed surface—was made the absorbent surface would seem to favour the idea that the downward flow in Mr. MURRAY's experiments was, partially at least, through the intercellular spaces. If so, to that extent it would not interfere with the upward current through the cells. Again, although all or a large number of cells in any particular part of a plant may co-operate and act in unison one with another under certain circumstances—as for instance, when a regular upward current is in action from the root to the leaves—yet nothing is more certain than that the cells have an individuality of their own. One cell, let us say, in the midst of its fellows, acts differently from the rest—it secretes, or it stores up materials of one sort or another, while the others do not. The physical and chemical actions in that cell are

necessarily very different from those which take place in its neighbours, and so, to speak familiarly, if a particular cell did not happen to require Mr. MURRAY's lithia solution it did not get it, while others perhaps got it because they could not help themselves—the "little rift within the lute," the nick, giving access to the fluid, where under natural circumstances it would not enter.

Looked at from a practical gardener's point of view, the question resolves itself very much into this: Are the leaves of any use further than as pumps to pump up sap from below, and evaporators to give it off from their surfaces? Unless we misinterpret Mr. MURRAY's views, the leaves, according to him, do little or nothing beyond this. Chemists and microscopists will hesitate a very long while before they assent to such a proposition, and the practical gardener a longer time still.

— Of late years the fashion of DOMESTIC FLORICULTURE has so largely developed, that gardeners find the supplying of the requisite cut flowers an onerous and trying part of their duties. Trusting to the ordinary flower-beds and borders scarcely suffices, as the plants so grown cannot supply the demand made upon their resources, whilst the destruction of the garden beauties is simply lamentable. The cultivation of considerable breadths of plants suitable for cutting, and specially for the decorative purposes to which cut flowers are chiefly applied, should form a feature in every good garden; and where this is done the result more than counterbalances any additional cost or labour involved. We are incited to pen these remarks, having recently observed in the Bedford seed grounds considerable beds of Foxgloves of the finest spotted kinds, many coloured Canterbury Bells with their long stems, singularly suitable for cutting and keeping a long time; and, not least, a fine breadth of Pentstemons, in abundant bloom and in great variety. Foxgloves and Canterbury Bells should at all times be treated as biennials, seed being sown in the spring of each year. The Pentstemon possesses a more perennial habit, and although not strictly a perpetual plant it can be made so by cuttings, from which plants can be produced freely; but really fine kinds are reproduced from seed in great abundance. The seed from which the bed in question was raised was sown under glass in a cool house in April, 1875, and the young plants put out into the open ground in June carried many fine spikes of bloom in the succeeding autumn. The next year they flowered freely all through the summer, and now they are literally a mass of flower. For vases and centrepieces the spikes of the Pentstemon are invaluable, not the less that a seed-bed produces a great variety of colours.

— At a recent meeting of the Botanical Society of France M. DUCHARTRE made a communication on the reproduction of tuberous BEGONIAS by means of cuttings rooted in water. Not only are roots produced in this way, but tubers also in the axils of the leaves resulting from the swelling of the axillary buds and shoots as one often sees in the Potato.

— Under the title of *Die Douglas Fichte*, Mr. JOHN BOOTH, of the Flottbeck Nurseries, has published an account of the DOUGLAS FIR, and other Firs of North-West America. The species particularly alluded to with reference to their introduction into Germany are *Abies Douglasii*, *A. Nordmanniana*, *Libocedrus decurrens*, *Cupressus Lawsoniana*, *Sequoia gigantea* (*Wellingtonia*). Photographs of these are given, and brief details of the size and appearance of the trees in their native countries, as also when cultivated. We shall probably have occasion to speak of this volume more at length on another occasion.

— The *Journal Officiel de la République Française* of the 26th ult. contains a very long report on the PHYLLOXERA in the French vineyards, which was presented to the Chamber of Deputies on May 4. The report details the characteristics and habits of the insect, the extent of its ravages, and the means adopted for its destruction or to ameliorate its effects. Unfortunately nothing essential is added to what has already been frequently and widely made public. Submersion is acknowledged to be a good remedy where practicable; the use of the sulpho-carbonates has been partially

FIG. 16.—VIEW FROM THE WOODY SLOPES AT CLIVEDEN, LOOKING TOWARDS MAIDENHEAD. (SEE P. 69)

successful; but the introduction of American Vines is the plan most successful. These Vines are either grown by themselves or as stocks on which may be grafted the finer varieties of French Grapes. The American Vines are either not attacked at all by the Phylloxera, or they are so robust as to be but little injured by it. With reference to the Phylloxera in English forcing houses, we may remark that within the last few days, the worst case of the leaf-gall formed by the insect that we have yet seen, came under our notice. So far as our experience is concerned the root form is much more frequent in this country than the leaf-gall.

— Under the title "INDUSTRIAL ART" Messrs. HARDWICKE & BOGUE have issued the first number of a monthly publication devoted to Art education as applied to practical purposes. It is well got up, and beautifully illustrated with tastefully selected woodcuts. We hope it may do something to save us from ugly whims and caprices, such as that which is so very inappropriately styled the early English style, wherein ugliness and discomfort are made to take the place of refinement and ease.

— The Rothamsted experiments on "CLOVER SICKNESS," if they do not demonstrate conclusively the cause of the deterioration, yet show by elimination that the primary cause of failure is not attributable to parasitic plants or insects, injury from excreted matters, or the shade of a corn crop, and that therefore it must be looked for in exhaustion of soil. The only means at present known of insuring a good crop of Red Clover is to allow some years to elapse before repeating the crop upon the same land.

— A short time since we were walking in a fine avenue of Yews, the pathway bordered on each side with a row of BUTCHER'S BROOM (*Ruscus aculeatus*), a plant worthy of all respect, so hardy and easy to please is it, and withal so sturdy, and in berry so handsome. We noticed that in the long walk in question scarcely a plant was left unutilized, and on it quizz we learnt that some miscreant herbalist, or his agent, was in the habit of obtaining entrance and cutting off the branches. For what purpose? we asked. The answer was, that it was supposed they were used for medicinal purposes. We doubted this explanation, though it is true the plant has medicinal properties, yet we never met with it in the herbalist's lists, and we know it forms no part of the regular practitioners' medicine equipments. A few days later we were told that the branches were used in the tobacco factories to sprinkle the dried leaves with salt and water, and that for this sprinkling purpose nothing answered so well as the Butcher's Broom. We should be glad to have this confirmed or refuted, as we had the story second-hand. We have seen it used by butchers in the country, and in schoolboy days were quite familiar with its use in flogging chilblains!

— A sixth edition of Canon HOLE'S *Book about Roses* (BLACKWOOD) has just been issued. It is somewhat thicker than before, as middle-aged books are apt to be, and it is adorned with a portrait of the author—no, we mean of his namesake.

— The grand conservatory and grounds of Messrs. E. G. HENDERSON & SON'S Pine Apple Nursery, Maida Vale, were on the evening of the 12th inst. the scene of a grand *fête*, botanical, musical, and pictorial, organised with a view of adding to the funds for enlarging St. Mark's Church, Hamilton Terrace.

— Well may it be said that Kent is the garden of England, when a fruit grower can send to market in one day 2500 pecks, about sixteen tons weight, of Strawberries, as was actually done last Wednesday week by Mr. VINSON, of Swanley.

— We hear that the Society of Apothecaries, in addition to the usual medals and prizes for botany and chemistry given to medical students, intends to offer a SILVER MEDAL for proficiency in BOTANY, to be competed for by LADIES only, in the hope of diffusing a more general knowledge of this useful and instructive science throughout the domestic circle, and of encouraging the teaching of botany in schools for the education of females. This is a very

laudable intent, one quite in keeping with all that the Society has hitherto done for the advancement of botany by maintaining its botanic garden, and one which we trust may be destined in due time to bear abundant fruit.

— We are requested to state that the gardens at Cleveland House, Clapham Park, will be open for the inspection of visitors on the first Friday in August, and on every succeeding Friday while the carpet-beds are in condition.

— NYSSA AQUATICA, the Tupelo tree, continues rare in England, although introduced nearly a century ago. This is due probably in some measure to the difficulty experienced in propagating except from imported seeds. It is perfectly hardy, and flowers freely, but it never matures its fruit in this country. On the Continent, in some parts at least, the same thing occurs. It is even hardy, as we learn from the *Berliner Monatschrift*, in the severe climate of Upper Silesia, where there is a tree upwards of 40 feet high, and one hundred years old.

— The *Berliner Monatschrift* for June contains a plate of the fine OLD WEYMOUTH PINE existing in the Royal Botanic Garden at BERLIN. It is about 70 feet high, and nearly 10 feet in girth 2 feet above the ground. The tree is of irregular but picturesque growth, and it has already suffered from the effects of high winds. Nothing certain is known as to its age, though it is probable that it was planted soon after its introduction into Europe. Unfortunately this interesting tree begins to show signs of decay, and for that reason the editors of the journal in question have hastened to secure its portrait.

— Dr. J. W. MOLL, Utrecht, has been conducting some experiments on the ORIGIN OF THE CARBON OF PLANTS, with the following results. A leaf, or a portion of a leaf, in an atmosphere destitute of carbonic acid, forms no visible quantity of starch, even if in organic connection or closely bordering on other parts of the plant, which are in a medium much richer in carbonic acid than atmospheric air. Therefore the superfluous carbonic acid within reach of any part of a plant does not cause any visible formation of starch in any other part with which it may be connected, and which is in a space deprived of carbonic acid. The formation of starch in a leaf, or part of leaf, is not visibly accelerated when it is attached to another part of a plant in an atmosphere in which carbonic acid greatly exceeds the normal proportion. The carbonic acid in the soil within reach of the roots cannot cause the formation of starch in the leaves of the same plant in an atmosphere from which carbonic acid is excluded, nor visibly hasten its production in the ordinary air.

— LASTHENIA CALIFORNICA is a fine showy golden-coloured annual that is well adapted for making a fine effect in the flower garden in spring and early summer. In spring gardens such a colour is much needed, and in warm sheltered spots, the plants, if raised from seed in August and kept in a cold frame during the winter, and then planted out in early spring in well-prepared beds, would in all probability bloom at the end of April and early in May. It has a close, compact habit of growth, which becomes completely covered with bright golden-yellow flowers.

— A correspondent of *Nature*, alluding to the propensity of sparrows to destroy yellow Crocuses in preference to those of other colours, says that this selection of colour is not confined to birds, as the RABBITS in his garden ate the RED and WHITE VERBENAS, and left the purple untouched. This happened for three years in succession, till the rabbits were kept out by wire netting.

— In the *American Agriculturist* a method of taking cuttings of bedding Pelargoniums, well known, but not practised so often as it might advantageously be, is thus described:—

"These when set in the open ground make a great growth after the severe heats are over, and afford an abundance of cuttings, but these, having grown rapidly, are very succulent, and if put into the cutting-bench in the ordinary way, would decay before they rooted. To over-

come this, and prepare the cutting, Mr. PETER HENDERSON hit upon a plan that worked capitally. Instead of taking the cuttings off at once, he cut the shoot half through, or 'tongued' it. This checked the further growth of the shoot, caused the wood to harden, and a callus to form at the cut surface; in a few days the cuttings were ready, and when treated in the usual manner formed roots at once."

— We are indebted to Mr. EDMUND TURNOR, M.P., for specimens of NEW ZEALAND FLAX (*Phormium tenax*) in flower. The plants were raised from seed brought by Mr. TURNOR from New Zealand in 1865, and though they have previously showed signs of flowering they have never thrown up fully developed flower-stems till this year, when on two plants there are eight or ten flower-stems, 6 to 8 feet in height—about their average height in their native country. Mr. TURNOR'S experience in the cold climate of Lincolnshire points to the conclusion that age has a good deal to do with the flowering of the plant. In any case the fact of its producing flowers in the open air in Lincolnshire is very interesting, and the more so as the plants are in no way protected in winter. Mr. TURNOR remarks that should any of the leaves turn brown and die after a severe frost, they are equally serviceable as bast for tying purposes.

— Another of the series of COLONIAL FLORAS projected by the late Sir W. HOOKER, and prepared at Kew, has lately been issued. The FLORA OF MAURITIUS AND THE SEYCHELLES has been prepared by Mr. J. G. BAKER, who has been assisted in the enumeration of the Palms and Pandani by Dr. BAYLEY BALFOUR, and in that of the Orchids by Mr. LE MARCHANT MOORE.

— The floricultural committee of the French Central Society of Horticulture has recently published its decision with regard to the gold medal offered by the Society for competition among the introducers of new plants. The conditions were that the plant should be generally recognised as of great merit, and introduced into the trade, or for sale, for the first time since January, 1868. After long consideration it was decided to award the medal for 1877 to Mr. A. LEVET, for the Rose Paul Néron.

— The clergyman who was the other day convicted of libelling a fellow-parson by sowing Mustard-and-ress in his garden in the form of the words that constituted the libel must be a singularly cold-blooded being. Men usually libel either in hot blood, or without waiting for deliberation. In this case the libeller must have had plenty of time for consideration whilst marking out his lettered design, sowing his seed, and, not least, awaiting its full development. Nine hundred and ninety-nine men out of every thousand would have put the hoe through this production of spite, long ere it was expanded into its full deformity. This man may have been a clergyman, but he was no Christian; he may have had a garden, but was no gardener. Our clerical gardeners—and they are not few—are as a rule kindly, genial gentlemen, who would scorn to tarnish the reputation of their gardens by such wretched exhibitions of malice as these. Mustard-and-ress may be slightly pungent, but it is neither sour nor bitter, and in being made the instrument of libel has itself been grievously libelled.

— According to the experiments made on the GROWTH OF BEANS by Messrs. LAWES and GILBERT, with different descriptions of manure, since the year 1849 up to the present time, the land being fallowed at intervals, it appears that mineral manures, especially potash, increased the products very much, especially during the earlier years of the experiments. Ammonia salts produced very little effect. Nitrate of soda has produced marked effects. Leguminous crops grown too frequently on the same land seem peculiarly liable to disease. When Wheat was grown eight times in alternation with Beans it was found that the crop of Wheat and the amount of nitrogen in that Wheat was nearly double that gained and detected in sixteen crops of Wheat grown consecutively in another field without manure. In other words, the Beans seem to have in some way contributed to the utilisation by the Wheat of a double quantity of nitrogen.

— The Spanish Moss, Old Man's Beard, and Long Moss of the Southern United States and the West

Ladies, *TILLANDSIA USNEOIDES*, figured in the July number of the *Botanical Magazine*, is well described in SLOANE'S *History of Jamaica* as a "mossie plant . . . with stalks the bigness of a thread, consisting of a thin skin, whitish, as if covered with a hoarfrost, having within that a long tough black hair, like a horse-hair . . . very often a yard long, hanging down on both sides from the branches of the trees they adhere to, being curled, or twining and winding within another, and making a show of an old man's beard (whence the name), or as if they were made to climb, which I never saw they did." Further on he says "it is used to pack up anything which otherwise may easily be broken, as cotton is sometimes made use of with us;" and again, "the inward black hairs of this moss's stalk are made use of by the birds called Watchpickets for making their curiously contrived nests hanging on the twigs of trees." To this description the Editor of the magazine adds that the Spanish Moss is a very widely distributed plant in the hotter parts of America, from Carolina to South Brazil, and on the Andes, hanging in bunches sometimes many yards long from the branches of trees. It has frequently been sent to England as packing for Orchids, but rarely alive, and it is not till quite lately that it has been successfully cultivated at Kew from plants imported (as packing) from Jamaica.

— At the meeting of the Prince Consort's Royal Association at Windsor on July 13, Messrs. SUTTON & SONS exhibited a beautiful collection of ANNUALS grown at their seed farm, Reading. It consisted of upwards of two hundred varieties, and attracted much attention from the Royal and other distinguished visitors.

— In the *Berliner Monatschrift* for June, 11. SCHARRER, Garden Inspector in Tiflis, gives an enumeration of PLANTS USED BY THE INHABITANTS OF TRANS-CAUCASIA AS VEGETABLES and as remedies for various complaints. Among the more noteworthy are the following, with their uses:—If there is much *Lolium temuleotum* in the grain used for making bread the root of *Helleborus abchasicus* is thrust into the newly-made dough, from which then a quantity of turbid yellow water flows, and the bread is thereby rendered wholesome. The fruit of *Physalis Alkekengi* is employed to colour butter. *Amaranthus viridis*, several species of *Rumex* and *Chenopodium*, and *Urtica urens* and *dioica* are eaten as vegetables. The young shoots of the Nettles, from 1 to 2 inches long, are highly esteemed and expensive, and the leaves of various kinds of Dock are collected and dried for winter use. *Dracocephalum moldavicum* is cultivated as a substitute for tea, and an infusion of the leaves of *Mentha Piperita* and *M. sylvestris* is also drunk instead of tea. The fruit of *Sambucus Ebulus* is used to make red wine of white; but wine thus treated is injurious to the health. *Achillea Millefolium* dried and reduced to powder is applied to open wounds. *Chelidonium majus* is given in cases of internal injury; and infusion of *Verbena officinalis* is a favourite febrifuge. *Galium Mollugo*, chopped fine and sopped in sour milk, is given to young geese; and *Tragopogon* species is collected when young, and eaten raw as a blood purifier.

— At the meeting of the Council of the ROYAL BOTANIC SOCIETY held on July 14, a SPECIAL GOLD MEDAL was awarded to Messrs. J. CARTER & CO., of Holborn, &c., for the novel and extensive collection of fine-foliated and flowering annual and other plants grown in pots from seed, which had been exhibited in the gardens of the Society during the month of June.

— The question of the NECESSITY OR UTILITY OF ANIMAL FOOD TO CERTAIN PLANTS seems to occupy the minds of many observers to the exclusion almost of the possibility of their being able to digest animal matter without its being necessary, or perhaps even advantageous, to their perfect development. As to the utility of animal food to plants, this is a point that no one will pretend to be able to determine by experiments on individual plants. To be conclusive, the experiments must be continued for a number of seasons or generations until some tangible result is obtained. Trials with individual plants appear to prove that animal food is not indispensably necessary to their complete nutrition, and this result, reasoning from analogy, might have been predicted. In tropical

and subtropical countries there are thousands of human beings who rarely, if ever, taste animal food, and it is contended that they are equally as strong and productive as the omnivorous peoples of the same regions. But even if we refuse to accept this view so far as the human races are concerned, it is worthy of consideration in any argument relating to plants. Because animal matter is not indispensable to plants, or because it does not appear to be useful in their nutrition, it does not follow that they are unable to digest and assimilate it. Nevertheless, many persons are seeking to prove or disprove the power of certain plants to dissolve and absorb animal substances by first of all determining whether the plants are able to live without. But as one fact cannot invalidate another, the simpler and more logical procedure would be to finally settle whether plants absorb animal matter at all, and then treat the question of the necessity or utility of it to the plant on its own merits.

— We have had occasion more than once to comment on the very miscellaneous bottles and other vessels considered good enough to exhibit cut blooms in at flower shows. Passing through the show of the National Carnation Society at the Royal Aquarium on Wednesday, we were struck with the form of bottle employed by the Society in question, and which is shown in the annexed sketch (fig. 17). It will be seen that the form is at once serviceable and pleasing. The cost is also slight. Messrs. BOURNE & SONS,

FIG. 17.—BOTTLE FOR SHOWING CUT-FLOWERS. (HALF REAL SIZE.)

Denhigh-by-Derby, we believe, supplied them to the Society at the rate of 18s. a gross. There really is no reason why flower shows should not be made as complete and perfect in their appointments as possible, and a little matter like that just alluded to makes a great deal of difference in the amount of gratification gained by the spectator.

— Professor REICHENBACH, being about to leave home for a short time, requests us to say that urgent letters may be forwarded to him, Poste Restante, Nice, France, till August 5. He further begs his correspondents to attach to each specimen they send him a label with a number and the initials of the sender, corresponding with similar information given in the letter accompanying the specimens.

— From an official statistical return issued by the Minister of Agriculture in France, we learn some details as to the ANNUAL FRUIT CROP OF FRANCE. The yield of stone fruit, Plums, Apricots, Peaches, Cherries, &c., in 1873, was returned at the value of £423,000, but the mean average is double this amount. Of seed fruit, Apples, Pears, Quinces, &c., the value was stated at over £2,500,000, but the average is about one-third higher than this. Other fruit trees, such as Capers, &c., produce about £300,000 more. The acreage under Vines is about 5 per cent. of the productive land, and comprises 2,583,000 hectares (6,379,309 acres). Algeria has also about 45,000 acres under Vines. Bavaria has 22,000 hectares under Vines; Rhenish Prussia, 20,000; Wurtemberg, 19,000; the Grand Duchy of Baden,

18,000; and the Duchy of Hesse, 8000. The total production of the German vineyards in 1872 was 2,000,000 hectolitres of wine. In Hungary there are 375,000 hectares under Vines, producing annually 12,628,000 hectolitres of wine; this is double the land under Vines in Austria, and the most considerable in extent after that of France. In Roumania there are 95,500 hectares under Vines. In Russia the average production is about 2,000,000 hectolitres [1 hectolitre = 22 gallons about] of wine. Spain has 1,000,000 acres under Vines. The annual production of wine in Italy is from 28,000,000 to 30,000,000 hectolitres, valued at £40,000,000. The entire world produces 150,000,000 hectolitres of wine—France produces on the average nearly half, of which only about 3,000,000 hectolitres are exported. Every year over 10,000,000 lb. of Grapes are sold in the city of Paris; what the consumption throughout the country is it is impossible to estimate. The export of fruits for the table from France were, in kilogrammes:—1871, 35,566,649; 1872, 25,995,955; 1873, 29,245,384; 1874, 63,743,540. The imports of table fruit, however, exceed the exports, ranging from 52,000,000 to 71,000,000 kilos. per annum. The exports of Chestnuts are from 4,000,000 to 6,000,000 kilos., and the imports about 3,000,000 kilos.

— We note the fact that our correspondent Mr. A. DEAN, of Bedford, was elected a member of the School Board for Feltham, Middlesex, on Saturday last, taking second place on the poll.

— In the *Journal of the Central Horticultural Society of France* is the report of a commission appointed by the Society to examine the FLORAL DECORATIONS IN THE APARTMENTS OF THE PALACE OF THE ELYSÉE on the occasion of a grand evening given by the Marshal MACMAHON. Some of the particulars will interest those who have to conduct the arrangement of floral decorations on a large scale. The decorations at the Elysée were designed and executed by Mr. DEBBIE, sen., who employed no fewer than 4780 plants in pots—from large Palms, Camellias, &c., to Primulas and Tulips, &c.—300 dozen bunches of green moss, and upwards of 350 yards of gilded rattan and other edgings. The large entrance vestibule was ornamented at the lower end with a group of large specimens of *Scaevola elegans* and *Phoenix leonensis*, their handsome shining silvery foliage overhanging a statue which was flanked by two splendid plants of *Dracena indivisa*, about 10 feet high, and clothed with leaves to the base. At the further end of the grand staircase of honour the light and delicate foliage of two fine *Cocos flexuosa* was reflected in a mirror, with profusely flowered Camellias. A specimen of a red-flowered variety of *Azalea indica* placed at the base of this mirror was exceedingly effective. On the landing of this staircase was a magnificent *Latania*, surrounded by two rows of bright red Primulas, which greatly heightened its beauty. In the saloon of the small buffet were twelve elegant groups of Lilacs, Roses, and Camellias, which were so light and well-selected, and so beautifully reflected in the crystal furnishings, that the effect was quite magical. The saloon of the *aisles-de-camp* was ornamented with two consoles furnished in the most exquisite taste with Tulips, Lilacs, Roses, and Hyacinths. In the large reception-room was a single large console bearing fourteen *Azaleas* of divers colours, four Camellias, fifteen *Heathes*, four Lilac Charles X., forty *Lycopodiums*, fifteen *Aphelandra* and *Gesneras* for a bordering, and two fine specimens of *Cocos flexuosa* in the centre, the whole forming a most seductive combination of colour, brilliancy, elegance, and lightness. The adjoining apartments were decorated in the same style in different pleasing combinations. In the hall of the Baths there was a very tasteful and brilliant combination of *Vriesia Glazouana*, *Aphelandra* and *Gesnera*, with *Cocos flexuosa* and white Lilac. The staircases to the apartments of Madame la Maréchale were ornamented with magnificent Palms, as *Phoenix*, *Areca*, &c., various Chinese Bamboos, 6 to 10 feet high, which contributed greatly to the lightness of the decoration; and *Phormium Colensoi* and *Veitchii*. In the Council-chamber there were two splendid consoles, in the shape of a boat, very tastefully decorated with Tulips and white Primulas. But the masterpiece of all was to be found in the large buffet, where light hangings had to be concealed as much as possible. For this purpose thirty large *Cocos flexuosa* were employed, alternating

with gigantic and rare vases filled with pyramids of Camellias of various colours. Azaleas, Phormium Colensoi, and other subjects contrasted well. Three hundred pots of Camellias formed a garland of brilliancy the eye was loth to leave. About a thousand Camellia flowers were stuck in the hangings not covered by the plants, forming a fairy picture. Lilacs and Tea Roses gave great elegance to the table-stands. Among other striking plants not yet named, Aralia Sieboldi, and Strelitzia angusta should be mentioned. If the report from which we have made the foregoing extracts is tolerably complete, the variety of plants used on this grand occasion was not great, and rare and costly plants easily damaged were altogether excluded.

— According to the *Bulletin de Statistique Muni-*

under the two other names of *Vanda lamellata* and *Aerides tessellatum*, an insignificant and worthless plant, a large quantity of which was also sold as being *Saccolabium ampullaceum*. Almost an entire importation sold as *O. Hallii* has proved to be *O. Lindleyanum*. An importation sold lately as *O. pulchellum majus* is the ordinary *pulchellum*, a very inferior flower. An *Aerides Fieldingii* (so sold and priced as sent) is only *A. suavissimum*. I could state twenty other cases, but these will suffice to indicate the not very creditable practice to which I refer. I am aware that it is not done with the knowledge or sanction of Mr. Stevens, who is always ready with information as to the persons by whom his customers are thus deceived, but I think more might be done for our protection against what are too often positive frauds. Thus, if the vendors will not warrant the plants as true, it might be so notified in the catalogues; as, for instance, "*O. pulchellum* (qy. *majus*)," or "supposed

were nearer fifty than fourteen. Last year, again—the smallest issue for some time—the number exceeded forty. Professed authorities should be accurate. π.

Lilium cordifolium.—Seeing from the *Gardeners' Chronicle*, page 51 of the present volume, that *Lilium cordifolium* is about to flower at Kew, probably for the first time in England, it may be of some interest to your readers to learn that in my nursery there are at present six plants of this Lily, throwing flower-stems. I remember that we had this Lily in flower in our nursery a long time ago, when it was first introduced, but the plants which are now about to flower are much younger than the plant which flowered here before. It is a general remark that in this country also *Lilium giganteum* is flowering in a younger state and more abundantly than usual, the flower-stems, however, are somewhat shorter than otherwise. Among other rare Lilies which have

FIG. 18.—VIEW IN THE PLEASURE GROUNDS AT CLIVEDEN.

capale of Paris about 3900 tons of fruit were sold in the *halles* of Paris during the year 1856. And during the same period about 2320 tons of vegetables, excluding Potatoes, were disposed of. The quantity of Potatoes is estimated at about 727 tons. The total number of laden vehicles which arrived in the square of the *halles* during the year was 594,574. During the month of June the maximum number, 84,751, was attained, and the minimum, 25,290, was in February.

Home Correspondence.

Naming of Orchids.—Amateur Orchid cultivators will, I doubt not, echo my complaint of the unscrupulous naming of Orchids by vendors at Orchid sales, and especially of a growing practice of sending the same plants into the market under different names. For instance, I and others have been imposed upon by *Saccolabium curvifolium luteum*, which proves to be the same as was sold

Hallii," or such-like. Buyers would then know what they were buying. As it is, we accept the unqualified statement in the catalogue as true, and feel not a little vexed when it proves to be false. Mr. Stevens might do much towards suppressing this wrong by adopting the plan I have suggested, and buyers would do more by insisting, in all cases of gross misstatements, upon the return of their purchase-money, which Mr. Stevens, I believe, always enforces on vendors who use his room for purposes of imposition. *Edward W. Cox, Meat Mount, Mill Hill.*

New French Roses.—Mr. Shirley Hibberd must have fallen into some error if he made the statement that in 1874 there were only fourteen new Roses sent here from France, and in 1876 again fourteen. He must surely have taken Eugène Verdier's issues alone, or the names adopted in some nurseryman's list. This last is a very uncertain test under any circumstances, as few trade importers now take the whole lot, as some formerly did. I have not at hand a copy of the lists I communicated at the time to more than one horticultural journal, but in each case they

flowered in my nursery I observe *Lilium Stantoni*, which was somewhat forced, and seems to be well adapted for such treatment. *J. H. Krelage, Haarlem.* [We believe we have seen this plant flowering many years ago, in Mr. Noble's nursery at Sunningdale. EDS.]

Arundo conspicua.—In the centre of a circular bed in the vegetable garden here is a plant of this hardy and effective subject with forty-five flower-spikes now in perfection (July 17)—some of them are 9 feet in height. The general appearance of this plant is sufficient to recommend it for ornamental work apart from the charming aspect which it presents when in flower with its fine stems surmounted with graceful pendulous tinted plumes; this object is surrounded with a ring of the old "Red-hot-poker plant," *Tritoma Uvaria*, also in flower, and this, with its fiery looking heads, makes a favourable contrast, which produces a charming bed. *G. T. Miles, Wycombe Abbey.* [Too much cannot be said in praise of the *Arundo*, which is valuable for its early blooming and graceful habit. EDS.]

Harrison's New Hybrid Musk.—I have come to entertain a high opinion of this as a decorative plant, and I look upon it as one of the most useful of the new productions of the past year. I write this much because I have heard statements tending to depreciate the plant. Soon after it was distributed I obtained four small rooted cuttings, and put them into a 24-sized pot. They have grown into a small specimen, 5 inches high by 7 or 8 inches through, and it is now completely loaded with large yellow flowers. I can count as many as fifty expanded at one time. It is one of the brightest and most effective objects in my greenhouse, and I think it will be largely grown as a decorative plant for summer and autumn. I have been testing its peculiar perfume with the common Musk, and find Harrison's hybrid to be as richly endowed as the latter. What a window plant it will make for cottagers when it becomes more widely distributed! Some of the flowers come handsomely blotched with yellowish brown. *Richard Dean, Ealing, W.*

Climbing Roses.—I can quite agree with "D., Deal," in his remarks about Réve d'Or. I have just seen a most vigorous specimen on a tall fence facing east, but somewhat protected by a house opposite. It is considered by the grower a splendid variety both for bloom, foliage, and hardiness. Another variety, equally good for climbing, is Belle Lyonnaise, which is bearing superb blooms on a fence facing east. Marchal Niel is also blooming very freely round the corner of a house facing south and east. Mr. George Paul may be right in calling Paul Néron ugly, but I think the word too strong, and the number and size of the blooms almost compensate for the somewhat imperfect form. *H. T. D., Cheltenham.*

Monœcious Araucaria.—I think the only instance we have of an Araucaria imbricata bearing both male and female flowers on the same tree is that noticed some years ago at Bicton. [See our figure at p. 291, 1873.] When visiting Castle Kennedy the other day, Mr. Fowler pointed out to me a tree carrying two catkins and six cones. To lovers of Conifers this is a thing of some interest. In the same avenue with the tree referred to above, there are trees bearing cones only, and other trees catkins only. *T. S., July 16.*

Walnuts Dropping Off.—On Saturday night we had heavy steady rain all night, with some wind. In the morning I found the ground under the Walnut trees strewn with young Walnuts. The wind, however, was not sufficient to do any harm to the Apple or Damson trees. This induces me to ask whether the Walnut tree is more liable to shed its fruit than other fruit trees? The number of the young Walnuts lying about seemed to me to be so large for one night's fall off one tree that I had them collected and counted. There was 1976 in all, which weighed 8 lb. The rain of yesterday has knocked down 250 more. The tree never has ripened much fruit, nor have I ever seen it with much on it, but this year, in spite of the quantity above referred to, there appears to be as much left as its full crop of previous years. The tree is about 40 feet high, and 5 feet 3 inches girth 4 feet from the ground. The bark is cracked for about 9 feet from the ground, but this does not seem to have affected the foliage, which looks beautiful. Could it affect the falling of the fruit? *J. A. C.*

Single Banksian Rose.—In your Rose Supplement you ask about the single Banksian Rose. I saw it beautifully in blossom in March last, in Mr. Hanbury's garden at La Mortola, near Mentone: it was the yellow variety. Mr. Hanbury did not know whence it was procured. Mr. Boissier, of Geneva, who had been there a few days before, was wonderstruck at it, and said that the existence of the single form in Europe was unknown to him. *J. V. V.*

Abies Engelmanni.—I have read Mr. Barron's letter respecting the above in the *Gardeners' Chronicle* of the 14th inst., and can fully bear him out in his remarks respecting the beauty and hardiness of this fine Conifer. I happened to have purchased at the same sale a parcel of this seed, which has turned out to be the fine variety alluded to. The plants are now fully 3 feet in height, and I have been sending them out freely for the last two or three years—the green under the name of A. Engelmanni, and the one of a more glaucous appearance under the name of A. Engelmanni glauca. I may state that both the varieties of the last two or three years have been great favourites of mine, and, as Mr. Barron mentioned, are totally distinct from Abies Menziesii. *John Waterer, Bagshot.*

Phoenix rupicola.—This interesting plant is figured in the *Gardeners' Chronicle* for last week, with a brief note which might lead to the impression that it is nothing more than a horticultural variety introduced into gardens with a distinctive name for trade purposes. Mr. Bull can so easily afford to

admit a reclamation, that I am sure he will permit me to place the actual history of this particular specimen on record. The Palm was originally discovered by Griffith, in Bhotan and the Mishmi Hills. Dr. Anderson found it in the Teesta Valley at a height of 400—1500 feet, and described it as a distinct species in the *Journal of the Linnean Society*, vol. xi., pp. 13, 14. His paper was read June 18, 1868, and in the same year he sent us a parcel of seed—the first which had reached English gardens—from which several plants were raised, and of these Mr. Bull had the plant now figured on March 15 of the present year in exchange for other plants. *W. T. Thiselton Dyer, Assistant Director, Royal Gardens, Kew.*

Trees and Shrubs at Colwyn Bay.—The annexed list of trees and shrubs now growing in my garden at Nant-y-Glyn, Colwyn Bay, North Wales, may be of use to anybody intending to plant in that neighbourhood. I have not included the more common and hardy trees in the list. Those marked * live but do not flourish, and those marked (w) are on a wall, generally facing E.S.E. The garden is on a slope facing the above quarter in a valley running down to the sea, and about 150 feet above it, and swept by N.E. winds from the sea, but protected by a high hill from the N.W. winds, which are the most injurious. The soil is mostly decomposed clay-slate (Wenlock shale) of various depths, the rock cropping out in places, and full of pieces of rock, which make it very dry and warm. The lowest temperature registered this year by one of Casella's minimum thermometers in a louver stand was 29°, in March. Zonal Pelargoniums in a sheltered spot were in good bloom on April 30. *Alfred O. Walker.*

Roses Duke of Edinburgh and Lord Clyde.—In reference to the remarks on these Roses at p. 54 of the *Gardeners' Chronicle* of last week, I hope I may be permitted to say that they were raised from seed by me in 1859 when a partner in the late firm of Adam Paul & Son. *William Paul, Paul's Nurseries, Waltham Cross.*

The Late Heavy Rains.—From Saturday A.M. to Monday at 9 A.M. we had 3.98 inches of rain, which since then has been supplemented by another half-inch. The Cherries are nearly all split open, and Strawberries are rotting in heaps. Truly this is a trying season for the "craft." *A. S. K.*

Village Botany.—You have alluded in your leader of the 14th to the introduction of botany in the village school of Hitcham by my father, the late Professor Henslow. Perhaps it might induce others to follow his example if they knew somewhat of his method. With this view I would refer your readers to my description of them in a paper, "Out-

† Two plants which flowered last summer and appear to be dead in consequence. ‡ Killed by moving in 1875. § Is a shrub here. ¶ Is a shrub here. ¶ Has made good growth this cold spring. †† Forms a large bush. ‡‡ Sometimes killed down to the ground. §§ Killed to the ground in winter except Madame Cornéliussen.

line of Professor Henslow's Practical Lessons in Botany," in the *Leisure Hour* for 1862 (p. 676). It is alluded to by Professor Oliver in his "Lessons in Elementary Botany," who also refers to the late Professor's pamphlet, *Illustrations to be Employed in Practical Lessons on Botany Adapted to Beginners*; this latter is, however, now out of print. In the same volume of the *Leisure Hour* (1862) will also be found accounts of the "Village Excursions" and "Hitcham Horticultural Shows," which were so eminently successful under the management of the Professor. I may add that I introduced botany on the same plans into the village school of Steyning in 1859 to 1861, and found it was quite as much appreciated by the Sussex as by the Suffolk children. The master and parents equally approved of it, chiefly, perhaps, on the score that it kept the children from idling and playing in the streets, inasmuch as they were most enthusiastic in collecting flowers in the fields during their play hours. *George Henslow.*

The Austrian Brier.—On a copper Austrian Brier, at least fifteen years old, this year there appeared a sprig of the yellow Brier. The branch was of last year's growth. No. 1 sprig was copper, No. 2 on the opposite side was yellow, No. 3 was again copper. In each case there was a whole bunch of flowers with their distinctive marks. Is the copper variety a sport from the yellow, or vice versa. *John H. Arkwright, Hampton Court, Leominster.* [The yellow is the normal form. Eos.]

Hoodia Barklyi.—A note in the *Gardeners' Chronicle* for last week mentions the flowering of this species in the Royal Gardens. The plant so called is, however, I believe, a new species, and will be described by me in the *Journal of the Linnean Society*. The original plant of Hoodia Barklyi—a species I described from imperfect materials obligingly supplied to me by Sir Henry Barkly, late Governor of the Cape—is now, as I learn from him, dead. The plant now flowering at Kew appears to me quite distinct, though in some respects intermediate between Hoodia Gordonii and H. Barklyi. *W. T. Thiselton Dyer, Assistant Director, Royal Gardens, Kew.*

Subterranean Cucumbers.—Last year in my garden I met with a subterranean Cucumber measuring 16 inches in length and 7½ inches in circumference. It weighed 2 lb. The colour was cream, except nearest the surface, which was slightly tinged with green. It had grown in shape somewhat like the letter S. To substantiate my remarks, I enclose you a paragraph taken from our local paper, the *Wills and Gloucestershire Standard* of May 27, 1876:—

"AN UNDERGROUND CUCUMBER.—A day or two ago, Mr. James Trinder, of the Fleece Hotel, accidentally discovered a vegetable curiosity in his garden. While examining a Cucumber bed he moved the earth, and, strange to say, a inches under the surface was a beautiful Cucumber, of singular growth, weighing 2 lb. The Cucumber was of cream colour, with a slight tinge of green on the part nearest to the top. It may be seen at the 'Fleece,' and is well worth the notice of horticulturalists."

It is my opinion that after the blossom was set my man, in adding more soil to the frame, had completely buried the fruit with the new soil, and, not being separated from its parent, it continued to grow until discovered. The colour is accounted for by the absence of light and air. Several tried to eat it, but found it too earthy in flavour. *James Trinder, Cirencester.*

Abies Menziesii Parryana.—Following Mr. E. André's invitation, after having once more compared my materials with Professor Parlatore's description, I am now fully convinced of my error in giving the name of *Abies commutata*, Parl. (A. Engelmanni), to the seeds which Mr. Roelz sent me as belonging to a beautiful variety of A. Menziesii. As I lay no claim to infallibility I candidly confess my error, and hope that Mr. André will now be satisfied. Still the two facts I wished to make public in my first article remain in full force—firstly, that the honour of introducing this fine Conifer for the first time belongs to Mr. B. Roelz; and secondly that the seedlings raised from those seeds Mr. Roelz sent home and distributed by me under the name of A. commutata are the very same thing as the plant in Professor Sargent's garden, at least if Mr. Roelz's distinct and repeated statement is to be trusted. *E. Ortgies, Zurich.*

Begonia weltoniensis.—This is one of the most useful plants for conservatory decoration during the spring and early summer with which I am acquainted, its dwarf habit, profusion of soft pink flowers, and elegant dark green foliage affording a little relief from the never-ending glare of Pelargoniums, Calceolarias, &c., which usually occupy such structures at that season of the year. Having been very successful in its growth a few details of my practice may interest some of your readers. After the plants

have done their duty in the conservatory I place them in a house or frame, giving them plenty of light and air until the stems become thoroughly hardened and almost leafless. They are then cut down, and the pots wintered under the stage in an ordinary greenhouse, where they get little or no water until spring. When they commence to grow, which will be about February, I shake them out of their pots, removing nearly all the old soil, and repot in a compost consisting of equal parts loam, fibrous peat, and leaf-mould, with a liberal addition of silver-sand. After potting they are placed in an intermediate house until they show flower, when they are staked out and removed to the conservatory, where they will remain fresh for several months. If grown from cuttings they should be struck as early in spring as procurable (and if wanted for specimens the flowers picked out the first year), repotting when necessary, and subjecting them to the ripening process when the season of growth is over. Under this treatment they will make nice bushy plants from 2 to 3 feet through the following year. *John Wilkes, The Gardens, Park House, Chealsee.*

Reports of Societies.

Royal Horticultural: July 17.—Lord Alfred S. Churchill in the chair. Mr. Andrew Murray announced his intention of deviating from the usual practice obtaining at these meetings of noticing all the subjects exhibited himself, by getting gentlemen possessing special knowledge of any particular branch of horticulture to communicate their experiences as occasion required; and in furtherance of this object he called upon Mr. G. F. Wilson to make a few remarks on the Lilies which he exhibited. Mr. Wilson first pointed out a specimen of the old *Lilium Martagon* album which when seen in perfection, as it usually was in Miss Hope's garden at Wardie Lodge, Edinburgh, was grand indeed, but it usually made a poor show in the neighbourhood of London. Next to come under notice was a large form of the fine white *Lilium longifolium*, which had been named *Wilsoni* by Mr. Max Leichtlin; *Lilium Krameri* was also a striking variety, and it had the great advantage of being grown easily out-of-doors; it was a very free grower, and withstood any ordinary amount of frost, besides being a very beautiful flower. The North American *L. pardalinum* was remarkable for the endless variety which the flowers exhibited in the shades of its crimson, the reflex of the petals, and the colour of the spots.—Colonel Trevor Clarke stated that he had identified a species of *Crinum* shown by Messrs. Veitch as *C. erubescens*, by means of a coloured illustration of that plant in an old volume of the *Botanical Magazine*. Colonel Clarke also commented upon some flowers of a pretty yellow hybrid *Begonia*, between *B. Pearcei* and *B. cinnabarina*, and which is being rapidly propagated at Chiswick for distribution among the Fellows.—Mr. Murray then commented upon other subjects exhibited, and the proceedings terminated.

SCIENTIFIC COMMITTEE.—Rev. M. J. Berkeley, Vice-President, in the chair.—This, the last meeting of the present session, was well attended; a large number of interesting objects were exhibited, while Mr. Murray's paper, printed elsewhere, excited much attention, the discussion upon it being unavoidably postponed. In the meantime a sub-committee was appointed to devise further experiments, and it was understood that every facility for the purpose would be rendered at Chiswick.

Amadou.—Rev. M. J. Berkeley showed a mass of fungus material similar to Amadou, and which had been extracted in lengths of 4 feet and upwards from the cavities in the trunks of *Eucalyptus obliqua*, at Goulburn, New South Wales. The specimens were sent by Baron von Müller.

Disease of Sugar-cane.—Mr. Jackson, of the Kew Museum, sent specimens of this, which has been alluded to on former occasions, but which is now known to be the work of a peculiar species of *Coccus*.

Hybrid *Elisena*.—Colonel Trevor Clarke exhibited flowers of a hybrid raised by him between the two so-called genera *Ismene* and *Elisena*. In the genus *Ismene* the stamens are straight, while in *Elisena* they are deflexed. Now in the hybrid the three upper filaments were declinate, the three lower ones straight or ascending.

Hybrid *Begonias*, &c.—Colonel Clarke showed specimens, showing that hybridisation could not be trusted to ensure a definite coloration—thus, × *B. weltoniensis*, pale pink, was a hybrid between *B. Dregei*, white, and *B. Sutherlandi*, orange, but has none of the orange colour of the latter. A second crop of × *weltoniensis* by *Sutherlandi* produced scarcely any other result. Colonel Clarke also showed a fruit of the Sikkim Cucumber, figured by us last year, and a cross between this and *Telegraph*, but the result was not noteworthy.

A New Condition of the Vinegar Plant.—Mr.

Worthington Smith stated that in some recent experiments on the action of light he had occasion to prepare the following mixture as a restraining agent (in place of pure acetic acid) for the development of negatives. Sulphuric acid, 3 oz.; granulated zinc, 4 oz.; gelatine, 24 oz.; and distilled water, 36 oz.; the whole being boiled in a closed vessel for three and a-half hours. For the purpose of the experiments seventy-five times the bulk of distilled water had to be added at the time of use. Mr. Smith stated that the original mixture permanently retained its transparency, but on the additional amount of distilled water being added the invariable result was that the mixture quickly became turbid and more or less filled with minute feathery bodies. These feathery bodies appeared within twenty-four hours and grew rapidly, at length traversing by long and extremely fine threads every part of the solution. The fungus bore no sort of fruit whilst in the dilute mixture, but on being transferred to syrup it floated on the top of the sugary solution, and immediately formed a film, which was a true Vinegar-plant. On the film being removed from the syrup and allowed to dry it produced *Penicillium crustaceum*. Mr. Smith exhibited the plants in question in the solutions, showing the different growths.

Pollen of *Fuchsia boliviana*.—The same gentleman exhibited a drawing of the pollen of this plant, and pointed out the curious fact, that instead of the pollen being triangular, as is common in nearly all the *Onagraceæ*, in this instance it was oval, and resembled in shape the pollen of *Fuchsia procumbens*.

Plants, &c., Exhibited.—By Mr. Berkeley, *Allium neapolitanum*; by Colonel Clarke, *Watsonia plantaginea*; from Mr. Woodbridge, cut specimens of *Cerasus ilicifolia* and *Suartia virginica*; from Mr. Maw, *Lilium polyphyllum* (a Sikkim form of *Lilium Martagon*), *Allium narcissiflorum*, *Linaria villosa*, and *Dioscorea pynaenica*—the latter a very remarkable plant from its isolated habitat, far away from the other members of the genus; from Mr. Elwes, a form of *Rosocoea purpurea* (?), with the flowers and foliage of the ordinary form, but without the tuberous roots. These differences may, it was suggested, be accounted for by different climatal conditions, and by the circumstance that the plant is sometimes an epiphyte; *Calopogon pulchellus*, a bog-Orchid from Canada, &c.; from Mr. G. F. Wilson, *Tropæolum speciosum*, a plant so beautifully grown in Scotland, so seldom seen in England. It was suggested that the roots should be kept moist, and largely manured with pig-dung; from Mr. Hemsley, leaves of *Rose* affected with *Rose Caddis*; from Mr. Cannell, sports of *Pelargonium*, showing dimorphic condition. These matters being disposed of, Mr. Murray then read his paper (see p. 72).

FLORAL COMMITTEE.—W. B. Kellock, Esq., in the chair. The meetings on this occasion were held in the old quarters—the Council-room, which was conveniently filled with an interesting assortment of plants, cut flowers, and fruits. First-class Certificates were awarded to Messrs. James Veitch & Sons for the new white *Hydrangea* Thomas Hogg, which has been shown on several previous occasions, and in better condition than it was to-day. Considering the lateness of the season for *Hydrangeas* in pots the plants were very fresh, proving, so far, its usefulness. To the same firm for *Begonias* Monarch and Mrs. Charles Scorer, both of the new tuberous rooted section. *Monarch* has fine dark metallic green foliage, a strong neat habit, and very large, broad, smooth rich scarlet-crimson flowers. The flowers of the dwarf-habited Mrs. Charles Scorer are of large size and splendid form, the petals being very broad, bluntly rounded, and of a deep crimson colour. To Mr. Mill, gr. to Lord Rendlesham, Rendlesham Hall, Suffolk, for *Ocoteoglossum coronarium* minutum, a miniature form of a very showy species, which we do not remember to have seen before. To Mr. Turner, Slough, for *Clove Carnation* Mrs. Matthews, a very fine white flower, deliciously scented, and a very free grower. To Mr. Croucher, gr. to J. T. Peacock, Esq., Sudbury House, Hammersmith, for the distinct and very handsome *Eagle's Claw Echinocactus* (see p. 749, vol. vii.), now provisionally named *E. grandicornis*. To Mr. B. S. Williams, for *Croton Queen Victoria*, a bold and striking new form, with leaves over 1 foot in length, and about 2 inches wide, lanceolate, deep metallic green, and heavily blotched and barred with orange and yellow, and flushed with fiery-orange. To Mr. Parker, Tooting, for *Lathyrus latifolius splendens*, a fine, rosy-purple Sweet Pea. Sir Trevor Lawrence, Bart., M.P. (Mr. Spyers, gr.), received a Cultural Commendation for a very fine plant of *Lelia Brysiana* (purpurata) with four splendid spikes of flowers. Sir Trevor also sent a fine healthy and well-developed plant of the singular *Brassavola Digbyana*, with seven very large cream-coloured flowers, the lips of which are very heavily fringed, which was recommended by the Council for a medal. Mr. B. S. Williams also contributed, in addition to the fine *Croton Queen Victoria* above-mentioned, several new plants, including *Lobelia Lilac Queen*, a dwarf,

very compact, and free-flowering variety of a very pleasing lilac or rosy lilac shade of colour. Messrs. Veitch & Sons also showed several other hybrid *Begonias*, and a group of the handsome slate-blue Mexican *Lisianthus Russellianus*; also a species of *Crinum* (*erubescens*) from the South Sea Islands, and fine examples of *Eulalia japonica zebrina*. Mr. J. Pithers, The Gardens, Munster House, Fulham, sent several seedling tuberous-rooted *Begonias*; and from Messrs. Downie & Laird, of Edinburgh, came a stand of fifty seedling fancy *Pansies*, remarkable for their size and the richness and variety of their colours. A vote of thanks was awarded. Mr. Turner again sent his new *Rose*, *Penelope Mayo*; and Messrs. William Paul & Son, Paul's Nurseries, Waltham Cross, received a vote of thanks for an interesting collection of *Roses*, either raised at or first sent out from that nursery. G. F. Wilson, Esq., again sent a contribution of cut blooms of various *Liliums*, including the handsome *L. longiflorum*. Mr. Wilson also showed a cut spray of the grand old *Tropæolum speciosum*, grown in the open air in his garden at Weybridge—a vote of thanks was awarded; as also to Messrs. Croucher & Boller, 73, South Row, Kensal New Town, for a group of a dozen and a half plants of the Old Man Cactus, *Pilocereus senilis*. Messrs Barr & Sugden sent a large and choice assortment of cut Lilies, English Ins, and several varieties of Iris Kæmpferi. Mr. J. Reeves, nurseryman, Acton, sent a grand lot of Balsams, the flowers being of remarkable size, very double, and bright in colour. A very fine specimen, with about one hundred spikes, of *Dendrochilum glumaceum*, came from Mr. Selwood, gr. to the Duke of Westminster, Eaton Hall, Chester, and was recommended for a medal. A very attractive collection of cut blooms of *Zonal Pelargoniums*, *Verbenas*, and *Sweet Williams*, came from Mr. Cannell, of Swanley, who also contributed a curiosity in the form of a *Pelargonium*, well named "Half-and-Half," about half of the pips being pure scarlet in colour, and the remainder pink; the latter, besides being totally different in colour, were also dissimilar in the shape and substance of the petals. It would be interesting to know, if this was a seedling, what were the parents, and if a sport, from what variety. Mr. Puttick of Acton also showed a choice group of market plants.

FRUIT COMMITTEE.—Mr. John Lee in the chair. The most meritorious productions that came under the notice of the committee to-day were half-a-dozen magnificent examples of Vines in pots contributed by Messrs. H. Lane & Son, Berkhamstead, and which were, if anything, finer than any that even these famous growers have shown before. Four of them were *Black Hamburg*, and the other two *Foster's Seedling*; there were about a dozen bunches on each, varying from 1 lb. to 3 lb. in weight, the berries being fine in size, though scarcely finished as to colouring. The Council, on the recommendation of the committee, awarded a Silver Knightian Medal. Mr. Turner, Slough, showed an excellent sample of a promising new *Pea* named *Dandie* *Diomont*, remarkable for the length of its curved pods and the fine size of the Peas. It is being grown this year at Chiswick, and will, no doubt, be heard of again. Mr. Turner also showed a capital dish of that excellent *Potato*, *The Schoolmaster*, grown on a south border. Messrs. James Carter & Co. showed a new *Pea* named *Little Wonder*, very dwarf, a great bearer, with the pods large and straight, and the Peas of capital flavour. As a field *Pea* this must prove a great acquisition. Another very good *Pea*, named *Hardy's Sequel*, was shown by Mr. James Hardy, The Seed Grounds, Bures, Suffolk. It grows about 4 feet high, and is very productive, the long pods being also very well filled. Mr. Ollerhead, gr. to Sir Henry Peck, M.P., sent a fine *Queen Pine*; and Mr. Burnett, gr. The Deepdene, sent two very handsome dishes of *Peaches*. From Mr. Miles, gr. to Lord Carrington, came a magnificent dish of *Bigarreau Napoleon* *Cherries*; and Mr. William Bull contributed a nice brace of *Cucumber Excelsior*, a rough-skinned and white-spined variety, resembling the *Telegraph* in form.

The National Carnation and Picotee Society's Southern Show: July 18 and 19.—The first Southern show of this Society was held on Wednesday and Thursday last in the Royal Aquarium, Westminster, and we are pleased to say that it was an eminently successful one, both as to the numbers staged, and the high quality of the flowers exhibited—a circumstance the more remarkable when we take into consideration that the season has been a most unpropitious one for this flower, and that the dates selected were quite a week too soon for Southern growers, and about three weeks too early to catch the Northern bloom. It was out of the question to expect any flowers from beyond the Trent, and as a matter of fact Northern florists were unrepresented, except in the persons of those redoubtable giants in floriculture, the Rev. F. D. Horner, of Kirkby Malzeard, and Mr. Ben Simonite, of Sheffield, whose presence proved a great source of gratification to

their Southern brother specialists. As regards the exhibition, it may be said that larger ones may, and no doubt have been, held, but it is very doubtful if so much quality has before been brought together. There were five competitors in the class for twenty-four Carnation blooms, not less than twelve dissimilar varieties, and the competition for the premier positions was very close between Mr. James Douglas, gr. to F. Whitburn, Esq., Loxford Hall, Ilford, and Mr. Turner, of Slough—so close, indeed, that the judges placed them equal 1st. The Hon. Sec., Mr. E. S. Dodwell, 11, Chatham Terrace, Larkhall Rise, S. W., was 2d; Mr. John Hines, of Ipswich, 31; and Mr. S. Bertram, Burgh Mills, Woodbridge, 4th—the flowers from all being smaller than those shown by Mr. Douglas and Mr. Turner, but in all other respects very good indeed, and especially Mr. Dodwell's, which were very correct, and had a charmingly refined appearance. Mr. Turner had splendid blooms of Sybil (Holmes), rose flake; Eccentric Jack (Wood), crimson bizarre; James Douglas (Simonite), purple flake; Mary Ann, rose flake; Ajax (Hextall), purple flake; Duke of Edinburgh (Abercrombie), scarlet bizarre; Merimac (Woods), rose flake; John Bailey (Dodwell), scarlet flake; John Keet (Whitehead), rose flake; Florence Nightingale (Sealey), purple flake; Sportsman (Heddesley), scarlet flake; Flora's Garland (Brooks), rose flake; Mr. Hextall (Simonite), crimson bizarre; Squire Trow (Jackson), purple flake; Annihilator (Jackson), scarlet flake; and Admiral Curzon (Easom), scarlet bizarre. Mr. Douglas' flowers were The Clipper, scarlet flake; Juno (Baldon), purple flake; Mars (Puxley), scarlet flake; John Keet, Marshal Ney (Headley), crimson bizarre; James Taylor and Sarah Payne (Ward), pink and purple bizarre; Sportsman, Admiral Curzon, Lord Raglan (Bowers), crimson bizarre; John Bailey, Earl of Stamford (Elliott), purple flake; Dreadnought (Daniels), scarlet bizarre; Samuel Newman, J. D. Hextall, James Douglas, Rose of Stapleford, Falconbridge (May), pink and purple bizarre; Rifleman, crimson bizarre; True Briton, scarlet bizarre; Premier (Milwood), purple flake; Mr. Battersby (Gibbons), scarlet flake; and Lovely Ann (Ely), rose flake. In the class for twelve dissimilar varieties Mr. Douglas was again awarded the 1st prize; Mr. E. S. Dodwell being again a good 2d, Mr. John Hines 3d, Mr. S. Bertram 4th; Mr. John Buxton, 321, Wandsworth Road, S. W.; 5th, and Mr. H. Catley, Bath, 6th. Mr. Douglas was here also in fine form with John Keet, James Douglas, The Clipper, Mary Ann (Holmes), purple flake; Marshall Ney, True Briton, Rifleman, Satisfaction, Admiral Curzon, J. D. Hextall, Premier and Sportsman. The three prizes in the smaller class for six went in the following order—to Mr. Arthur Medhurst, 32, Priory Road, Wandsworth Road; Mr. William Ellis, Wandsworth Road; and Dr. Abercrombie, of Cheltenham. In the 1st prize stand the flowers shown were James Douglas, Mars (Hextall), scarlet bizarre; John Bailey, John Keet, Admiral Curzon, and J. D. Hextall (Simonite). This which should have been the largest class in the show, was, strange to say, the poorest as regards numbers. The competition was very good in the class for single specimens of the various types, and the following awards were made:—Scarlet bizarres: Mr. Douglas 1st and 2d with Admiral Curzon, and 3d with Campanini (Turner); Mr. J. Hine 4th, with Lord Ranelagh (Halliday), and Mr. Douglas 5th, with another bloom of Admiral Curzon. Crimson bizarres: Mr. Turner 1st, with Unexpected, and 2d with Mr. Hextall (Turner); Mr. Douglas 3d, with Marshal Ney, 4th with J. D. Hextall, and 5th with Graceless Tom (Wood). Pink and purple bizarres: Mr. Turner, 1st, 2d and 4th with James Taylor, and 3d and 5th with Sarah Payne. Purple flake: Mr. Turner 1st, with True Blue (Taylor), and 2d with James Douglas; Mr. John Hines, 3d, with Mayor of Nottingham (Taylor); Mr. Turner 4th, with James Douglas, and 5th with Ascendant (May). Scarlet, flake: Mr. Turner 1st, with Sportsman; Mr. Douglas 2d and 3d, with the same fine variety; and Mr. Turner 4th and 5th, with Annihilator. Rose flake: Mr. Turner 1st, 2d, and 3d, with Sybil (Holmes), 4th with Mary Ann, and 5th with John Keet. The premier Carnation in the show was a lovely flower of Holmes' Sybil, shown by Mr. Turner.

PICOTEES were equally as well shown as Carnations, both as to numbers and quality, and nearly the same growers competed in the several classes. In the leading class for two dozen blooms Mr. James Douglas had no rival to share the honour of being 1st, though Mr. Turner was a very close 2d, Mr. E. S. Dodwell being a good 3d, and Mr. T. S. Ware, Tottenham, 4th. Mr. Douglas' flowers were grand in every respect, and so indeed were Mr. Turner's, which were, however, a trifle smaller than the amateurs'. The varieties shown by Mr. Douglas were Princess of Wales (Fellowes), red-edged; Mrs. Bower (Bower), red-edged; Mrs. Allcroft (Turner), rose-edged; Pico (Jackson), heavy purple-edged; Obadiah (Kirtland), heavy scarlet-edged; Mary (Simonite), light purple-edged; John Smith heavy red-edged; Edith D'Ombrain (Turner), heavy rose-edged; Prima

Doona, purple-edged; Ann Lord (Lord), light purple-edged; Miss Small (Fellowes), heavy red-edged; Mrs. May, Mrs. Little (Hooper), light purple-edged; Lord Valentin (Kirtland), heavy red-edged; Ethel (Fellowes), medium rose-edged; Ganymede and Juliana (Turner), heavy-edged scarlet. Mr. Douglas also came in 1st with twelve, showing splendid blooms of John Smith, Mrs. Allcroft, Mrs. May, Mrs. Bower, Ann Lord, Pico, Mrs. Summers (Simonite), heavy purple-edged; Juliana and Mary. Mr. E. S. Dodwell was a good 2d, Mr. J. Buxton 3d, Mr. S. Bertram 4th, Dr. Abercrombie 5th, and Mr. John Hines 6th. In the class for six the highest award went to Mr. Arthur Medhurst, who had medium-sized but very refined blooms of Lenora (Fellowes), heavy red-edged; Juliana, Mrs. Niven (Marris), heavy purple-edged; Clara, red-edged; Alice (Lord), light-edged purple, and J. B. Bryant (Ingram), heavy red-edged. Mr. William Ellis, Wandsworth Road, came in 2d; and Mr. Gibson, gr. to T. F. Burnaby Atkins, Esq., Sevenoaks, 3d. The single specimen classes were here also well represented, and the prizes were awarded in the following order:—Red, heavy-edged: 1st, Mr. S. Bertram, with Colonel Clark (Norman); 2d, Mr. Douglas, with Princess of Wales; 3d, Mr. Turner; and 4th, Mr. John Hines, with the same variety; and 5th, Mr. Turner, with the Rev. F. D. Horner (Fellowes). Only one light red-edged variety was shown, *i.e.*, Thomas William (Cloudy), shown by Mr. Turner. Purple, heavy-edged: Mr. Turner 1st with Leah, and 4th with Cynthia (Turner), light-edged usually, but medium in this instance; and Mr. Douglas 2d and 5th with Chanticleer (Fellowes), and 3d with Mrs. May. Purple, light-edged: 1st and 3d, Mr. Douglas with Mary; Mr. Turner 2d with Cynthia—very correct here; 4th with Mrs. Harland, and 5th with Alice (Lord). Rose or scarlet, heavy-edged: Mr. Douglas 1st with Mrs. Allcroft, and 2d with Ethel; 3d, Mr. Turner, with Miss Wood, 4th with Mrs. Allcroft, and 5th with Miss Wood. The premier Picotee was John Smith, a very fine heavy red-edged flower, shown in Mr. Douglas' stand of twenty-four.

Several varieties were shown for certificates, but these were only awarded to two, viz. Lady Louisa (Abercrombie), a pretty heavy-edged light rose flower, and Clove Carnation Mrs. Matthews (Matthews), pure white, very sweet, and a rare grower. Both of these were shown by Mr. Turner. Yellow-ground Picotees were very poorly represented, and concerning them it need only be said that the prizes went to Mr. T. S. Ware, Mr. H. Catley, and Mr. Henry Hooper. A fine lot of blooms were shown in the miscellaneous classes for selfs or Fancies, for the most part "good flowers gone wrong" in the matter of colour, but very showy for all that. The awards for twenty-four blooms went to Mr. Turner, Mr. Douglas, and Mr. Buxton; and for twelve to Mr. Turner, Mr. Dodwell, and Mr. Hooper, of Bath.

A ROSE SHOW, but not the show of the season, was held in conjunction with the above, the prizes being offered by the Royal Aquarium Company. In the way of comments or details we need say but little, the display being only of moderate dimensions, and, owing to the lateness of the period, and the late heavy rains, there was a great lack of quality. The Hereford growers had, on the whole, the best of the competitions, the three highest prizes offered going to that city. With forty-eight single trusses Messrs. Cranston & Co. were well 1st, Mr. B. R. Cant, of Colchester, coming in 2d, and Messrs. Paul & Son, Cheshunt, 31. Mr. Keynes, Mr. Turner, and Mr. Bennett, of Stapleford, also competed, but at a manifest disadvantage. Messrs. Cranston & Co. were also 1st for twenty-four trusses, Mr. Turner being 2d here, and Mr. Cant 3d. Mr. W. Corp, of Oxford, was the most successful competitor in the next two classes, taking 1st prizes for twenty-four and twelve respectively, Messrs. Cranston & Co. coming in 2d, and Mr. H. Bennett 3d in the first-mentioned class; and Mr. Turner and Mr. Bennett in the latter. The leading amateur exhibitors were Mr. Jowitt, of the Old Weir, Hereford; and Mr. R. N. G. Baker, of Heavitree, Exeter—the first-named gentleman being 1st for twenty-four singles, and Mr. Baker occupying the same honourable position for eighteen distinct single trusses. For twelve distinct varieties, three trusses of each, the Rev. E. N. Pochin, of Leicester, was 1st. Mr. B. R. Cant sent the finest stand of a dozen Teas or Noisettes, and in a class for six blooms of any variety of Tea or Noisette Rose, Mr. J. Tranter came in 1st with some rich golden-yellow coloured Maréchal Niels, while in a corresponding class for Hybrid Perpetuals Mr. Cant was 1st with Alfred Colomb.

Amongst the miscellaneous contributions to the show were a fine group of Liliun auratum and a large collection of showy Verbenas from Mr. Turner, a large collection of Carnations and Picotees and Pansies from Mr. Ware, of Tottenham; a fine stand of cut Verbenas from Mr. Cannell, of Swanley; and a basket of plants of the charming Mauve Beauty Stock from Mr. Richard Dean, of Ealing. Messrs.

H. Lane & Son, of Berkhamstead, also showed the same half-dozen pot Vines exhibited by them on the previous day at South Kensington, and we need scarcely say that they proved a great source of attraction.

Ludlow Rose Show.—Seven gated Ludlow has distinguished herself once more in the annals of history—she has held a Rose show all to herself. What a picturesque town it is! Crowned by the most perfect palatial ruin in England her streets creep terrace upon terrace up the wooded hill which rises abruptly from the bed of the River Teme. Within walls, over which of yore floated the banners of victorious Stephen—where the Edwards, Henry VIII., and Elizabeth held court—where Prince Arthur (at all events an important part of him) lies buried—the modern archers of the Teme celebrate their innocent orgies, and return-tickets sow broadcast shells of the wonted hard-boiled egg.

In 1460, while the Wars of the Roses were raging, Ludlow was the rendezvous of the Yorkists, and it was at a distance of only a few miles that Pembroke fought his losing Battle of Mortimer's Cross. In memory of these battles the pretty little prehistoric Rose (Prenestina variegata), so well known by its scarlet streaks, was named York and Lancaster, combining as it does the red and white, their distinctive fancies. Who knows that it was not introduced in the button-hole of one of the "choice body of veterans from Calais," who were brought over by the Earl of Warwick and quartered within these seven gates? Peace to their ashes! And what would say the modern disciples of bones, nitrate of soda, guano, soot, and the like, to the instructions given 120 years ago in *Et en, or the Compleat Gardener*, for the proper cultivation of this and that other miraculous variety, the "double red?" I give them: "No compost is needed for them, as common garden mould perfectly answers the purpose."

Later on her beauties will adorn the portfolios and walls of many a high-art collection, as long as water-colour shall endure by Varley, David Cox, Leitch—in short by every artist whose good genius has guided him and his easel within sight of Ludlow Castle. But a modern war of the Roses has been fought. A small faction (now, we hope, defunct) arrayed itself against the promoters of this Rose gala. Did they forget that Roses, though certainly during that short period do reign supreme, usurp only one fortnight? Are not the remaining fifty weeks of the year enough for the other branches of horticulture? Oh, monster of the green eye, it is not the first time you have dallied with an emblem the purity of which should have placed it beyond your venom!—for is it not written anent "Lord Thomas and the faire Annett,"

"He had a Rose into his hand,
He gave it kisses three,
And, reaching by his nut-brown bride,
Laid it on Annett's knee."

(N.B.—The "nut-brown bride" is discovered hanging over the fair Annett holding a dagger at point, fully a foot long, but she was none the worse for it.) However, pluck, and the ably directed energies of a lady who lives not 100 miles from Ashford Hall won the fight, and the trying tree was declared to be the Assembly Rooms, on July 12, 1877.

Next year (for this is to be an annual event) the committee would do well to adopt the card-trick of the National, for I heard an exhibitor say that the jam on the double entry label was not honey to the lip; moreover, it was the cause of a block at the narrowest part of the approach.

The general management and ubiquity of the officers in charge was beyond praise, and could not have been excelled had they been the most practised veterans, for which exhibitors were very grateful—it matters much.

Of novelty *quâ* Rose there was none. Among the nurserymen—whose boxes were judged by the Rev. C. H. Bulmer, Mr. J. H. Arkwright, and Mr. T. Jowitt—Lee, of Lyonshall, took three 1sts, with fresh and well set up flowers; Cranston, Griffiths, and F. A. Dickson, of Chester, taking the 2ds and 3ds. Such a disposition of prizes reminds one of the old rhyme, slightly altered—

"To teach his foreman Roses his leisure he'd employ
Until at last the old man was beaten by the boy."

Lee and Griffiths are both sports from Cranston (I do not the least detract from their high merit, but the fact is that Mr. Cranston was exhibiting at Clifton and a third place on the same day. But what a dodo to be in three places at once! He always goes on with a good sport at any risk.

Among the amateurs (open), Mr. Jowitt was 1st for thirty-six and twelve, and Mr. J. H. Arkwright for twenty-four and twelve Maréchal Niels; Miss Tarant and Rev. C. H. Bulmer taking the 2ds and 3ds. The prizes for local amateurs were taken by Mr. Berrington, Mr. Keddie, and Miss Hall. It will take another year to bring cottagers to the scratch. Mr. Arkwright sent an interesting collection of twenty-four varieties of real old ones (half-a-handful

of each)—Persian yellow, with the straw-coloured and pink Briers in cross, supported by Bourbon Noisette, Provence, Moss, Damask, and Boarsault; but to name them, who could do it, unless perchance Mr. Curtis? The absence of prizes for trebles induced several to stage their spare Roses with good effect.

The Bay-leaf for floral decoration incited but few to action, but to see Miss Evans' lovely vase was worth a journey—simplicity, grace, and treatment of tone were throughout predominant. Yes, simplicity can be predominant. Once an enthusiastic amateur went to a celebrated artist (say Frederick Taylor), and thus he spake: "Give me lessons; I don't want much, only just to make a sketch with a few lines, as you do." Quoth the great man: "Go home again; this result is from the laborious study of forty years." The art is one of leaving out lines, not of cramming them in; but every stroke must be in its right place. Is it so also of the decoration of a vase? Materials, flowers, foliage, glass were all there, but with that one exception all I saw was either a crude formality or a simple bit of haymaking. Yes, there was one other—a leaning tower of Pisa, a toss-up whether the centre of gravity fell within or without the vase.

I have heard since that the practice of detaining Poses obtained at the close of the show. For reasons which I need not give, this must not be. In Edward IV.'s time the privilege of trying and executing culprits within herself was granted to Ludlow. Rose stealers beware!—this faculty may be revived.

But you are yawning. Ludlow has stuck one more feather in her cap. *Correspondent.*

Royal Caledonian Horticultural: The Rose competition and summer flower show of this Society took place on Wednesday, July 11, in the Music Hall, Edinburgh. In the Rose competition the number of entries was greatly restricted to what was expected, on account of many of the nurserymen and gardeners having no blooms in a sufficiently advanced state. If all outdoor flowers were deficient in numbers, the display of those raised under glass was far above average merit and very attractive. Of ornamental foliage plants and Palms there was an excellent exhibit. The Fuchsias were well-grown and in capital condition, but the Pelargoniums were hardly up to the mark. The Cape Heaths were exceptionally fine. Mr. Walker, of Lanark, showed some dainty Orchids, including *Odontoglossum Alexandræ*, *Dendrobium nobile*, and *Phalenopsis Ludemanniana*, the latter with over twenty flowers. The collections of Ferns was one of the features of the exhibition, and seldom before has so uniformly fine a lot of this favourite plant been got together at a Caledonian show. The cup given by the Lawson Seed and Nursery Company for the best six exotics fell to Mr. James Green, gr. at Murrayfield, with the following six varieties:—*Todea superba*, *T. intermedia*, and the *Adiantum cardiochlaena*, *assimile*, *gracillimum*, and *pedatum*.

In the Rose competition the well-known name of Hugh Dickson, of the Belmont Nursery, Belfast, once more headed the list of honours. On this occasion he had fewer rivals than formerly to contend against—the only other nurserymen who tried conclusions with him being Messrs. Robertson & Galloway, Glasgow, and Mr. Thomas Smith, Stranraer. Mr. Dickson's prize Roses sustained the high reputation of the Belmont Nursery. The gem of the collection was undoubtedly Beauty of Waltham, with large and well-disposed petals of rare merit. Others, however, were not far behind it, among which may be noted *Camille Bernardin*, the Duke of Edinburgh, *La France*, *Le Havre*, and *Etienne Levet*. Messrs. Robertson & Galloway's lot was also exceedingly good. To Mr. Smith, Stranraer, who, by the way, was not in time to have his entries scheduled, the judges made an extra award for a lot of twenty-four Roses which were in every way deserving of the honour accorded to them. In the gardeners' and amateurs' class Mr. Parlane came to the front with an excellent two dozen from the gardens at Golffhill. One or two looked nearly as good as some in the Belfast cases, such as *La France*, *Dupuy Jamin*, and the Duke of Edinburgh. The fragrant Tea Roses were a very choice array—one bloom, named *Rubens*, in the case of Mr. McCulloch, *Phantasie*, being in its way a perfect beauty.

The fruit shown was not plentiful but was of excellent quality, though many of the Grapes were far from ripe. Mr. Johnston, Glamis, again asserted his superiority as a grower in this department, his collection being first-class. To Mr. McConnachie was deservedly awarded the 1st prizes for *Hamburg* and *Muscat Grapes*, both being ripe and beautifully finished. The plate of Peaches from Whitehall which took 1st also deserves a word of notice. There were comparatively few exhibits of vegetables. As usual, several of the nurserymen of the city contributed greatly to the adornment of the hall by sending exhibition plants from their greenhouses. The orchestra

and the front table were mainly occupied by the Lawson Seed and Nursery Company, with a goodly collection of Palms and other ornamental plants. Messrs. Dickson & Co., Waterloo Place, were strong in fancy Pansies and Violas; Messrs. Methven, Princes Street, had a somewhat miscellaneous assortment of plants in pots and cases, conspicuous among which was a collection of Iris; while Messrs. Downie & Laird exhibited some fine Pansies, Violas, and Pelargoniums. First-class Certificates were given to Messrs. Dickson & Co. for their white bedding *Viola Nonpareil*, for the show Pansies *Pilrig Beauty* and *Mrs. Thomson*, and for the following fancy Pansies:—*Mrs. Cree*, *Mrs. Ingram*, *William Blackwood*, and *Louisa Milne*. Messrs. Downie & Laird also obtained a First-class Certificate for the underrated fancy Pansies:—*Mrs. Currie*, *Mrs. Jamieson*, *Mrs. Stevenson*, *Mrs. Wolfe Murray*, *Lady Scudamore Stanhope*, *Lady Hay*, and *Miss Hay*. *Scotsman.*

Wanstead and Leytonstone Floricultural: July 5.—This Society held its eleventh annual exhibition in the grounds of J. Biggs, Esq., Oak Hall, Wanstead, and speaking by comparison with its predecessors it well maintained its position in all respects save vegetables, which have been but very indifferently shown in any part of Essex this season. The chief classes for plants were well contested. Alderman Finnis (Mr. Simmons, gr.), having been very successful with stove and greenhouse plants, *Fuchsias*, *Tricolor Pelargoniums*, *Gloxinias*, *Achimenes*, and vegetables, &c. For fine-foliage plants, for which the heaviest prizes in the show were offered, S. Ellis, Esq. (G. Hay, gr.), was 1st, with large showy examples. The class for six *Coleus* was warmly contested, the highest award being carried away by J. Harrold, Esq. (W. Knott, gr.), Duke of Edinburgh being very conspicuous amongst them. Splendid examples of *Lycopodiums* came from W. Fowler, Esq. (Mr. Monk, gr.), some of which, even *L. apoda*, were 2 feet in diameter, and perfect examples of cultural skill—the same exhibitor being 1st with *Hydrangeas*, specimen Ferns, *Crotons*, bouquets, &c. Some very fine examples of *Carnation Souvenir de la Malmaison* were shown by A. Geere, Esq. (Mr. Frost, gr.), which proved quite a feature at the exhibition. Amongst amateurs Mr. Abbott had some excellent Ferns. In the classes for cut Roses Mr. Bristow, Little Blake Hall, proved a worthy exhibitor, distancing his competitors.

Perhaps one of the best filled and contested classes consisted of that "open to all," wherein a group of fifteen plants, flower and foliage, to be arranged for effect and quality, were asked. The chief prize fell to Mr. Monk, gr., as above. We were pleased to see at this end of the tent, a well flowered specimen of the pretty *Asclepias curassavica*. The best "design of a flower garden, size 5 feet by 3 feet," was contributed by Mr. Windebank.

An admirable collection of wild flowers was staged by the Misses Loscombe and G. A. Stable, both the Latin and English names very legibly written being attached to each specimen. We were gratified to see amongst them the lovely old flowering Rush, *Batomus umbellatus*, and to be assured by a reverend gentleman present that this fine old British plant really exists in the neighbourhood. The single vase for a drawing-room table, by Miss Biggs, worthily took the 1st prize—that for dinner-table decoration, put up by Miss Bland, taking a similar award. Perhaps the finest six pots of Strawberries we ever saw staged were those shown by R. R. Cotton, Esq. (J. Beadle, gr.), whether for size of fruit, their abundance, or the immense foliage and robustness generally;—they were exceedingly fine. Fruits were fairly well shown:—J. Biggs, Esq., Oak Hall (J. Cassell, gr.), being 1st with Black Grapes; Mr. G. Hutchinson (Mr. Thurgood, gr.) staged splendid crimson Queen Strawberries, the Peaches of G. Wilkinson, Esq. (Mr. Sayers, gr.), being as good Royal Georges as any we recollect to have previously seen staged. *W. E.*

Newcastle Botanical and Horticultural: July 11 and 12.—The great summer show of this Society was held in the Leazes Park, a portion of the Town Moor, and a more beautiful spot for a flower-show cannot well be found, more especially when the weather is favourable. The ground most suited to the show lies high and much exposed to winds—a matter of great importance in selecting tents for the purpose; in this respect the committee seemed equal to the occasion. The first sight would impress one of a huge winter-garden, or a large tent covered in with span or ridge-and-furrow roofing. The larger specimens were arranged on tables near the ground, whilst others for cut flowers and fruit were fixed at suitable heights, in some cases a little too high—a defect easily remedied another year. Although the Newcastle show has had some good meetings and caused great excitement in the North, on this occasion it has even surpassed itself, and this to a certain extent is the result of issuing a liberal schedule—in fact I think it safe in saying that it contained more special prizes than any other schedule issued. There is another

important feature here that it would be well for other societies to imitate—that is, to secure sufficient funds by subscription to cover the expense of the show: a capital plan of providing against a rainy day.

Unfortunately for the local exhibitors the leading prizes were taken by distant exhibitors. The 1st prize for six stove and greenhouse plants, £10, went to Mr. Tudgey, gr. to T. F. G. Williams, Esq., Henwick Grange, Worcester, with splendid plants of *Anthurium Scherzerianum*, *Genetilis tulipifera*, and others equally fine; 2d, to Mr. T. Wilson, Normanby Hall, Middlesborough: in this collection were some fine *Ixoras* and *Allamandas*, well grown and splendidly flowered. Mr. Moulton, gr. to Lord Ravensworth, showed a splendid plant of *Ixora Willamsii* in his collection: this proves to be the best *Ixora* in cultivation. The class for three flowering plants were much of the same character as the six, the 1st going to Mr. Sleighthole, Armley, near Leeds, who had one of the best flowered *Stephanotis floribunda* seen this season. The ornamental-foliage plants were numerous and exceedingly fine, the 1st prize going to Mr. Tudgey, with well grown specimens; 2d to Mr. Noble, gr. to J. Fry, Esq., Darlington. In this collection was the finest plant of *Croton Johannis* that we have seen, well coloured. This will make a splendid exhibition *Croton*.

The class for six Ferns brought several exhibitors.—Mr. Tudgey 1st, with six neat-grown plants of *Gleichenias*, *Adiantum gracillimum*; Mr. Noble 2d, Mr. Thompson 3d. The class for three Ferns were nice, well-grown plants, and a number of competitors. The class for three *Ericas* was only middling, the 1st and 2d going to Mr. Tudgey. Show *Pelargoniums* were very fine, Mr. King, of Bedale, taking 1st, 2d, and 3d in the same class. This is a matter that has happened in other classes, and would seem worth the attention of the committee. There were also some nice collections of *Zonal Pelargoniums* shown. For six *Coleus* in 6-inch pots there were sixteen exhibitors, one of the most difficult classes the judges had to deal with. Mr. Moulton 1st, Mr. Sherwin 2d, Mr. Stockley 3d. *Lilium auratum*, two pots, 1st to Mr. Sleighthole, of Leeds, were gigantic plants, at least 8 feet high and well-flowered. *Dioner-table* plants brought sixteen competitors. This is a class of plants worthy of encouragement, as it forms a very interesting feature in a flower show, and it also provides a useful plant for home decoration. Cut flowers (forty-eight Roses), brought ten exhibitors, and of note, from a distance—the finest lot ever exhibited in Newcastle: Mr. Turner, of the Royal Nurseries, Slough, had the honour of taking the 1st prize; Messrs. Davidson & Co., Hereford, 2d; Messrs. Cranston & Co., Hereford, 3d. Class 19, thirty-six Roses: Messrs. Cranston & Co. 1st, Mr. Turner 2d, Messrs. Davidson & Co. 3d. Class 20, twenty-four Roses: Messrs. Cranston & Co. 1st, Mr. Turner 2d, Messrs. Davidson & Co. 3d. There were many other classes of Roses, which were shown in excellent condition, and formed a very important feature of the show.

Table Decorations.—The 1st prize in this class was a magnificent cup offered by the President, Major Wood, worth 25 guineas. This was taken by Mr. Thompson, gr., South Hill, Chester-le-Street. This was decided by all the judges present to be the best they have ever seen, and more especially the arrangement of the *epergnes* for the centre. The other prizes taken—2d, Mr. Gellenden; 3d, Mr. Sanderson; 4th, Mr. Methven; 5th, Mr. Edmondson. These were all put up in a creditable manner, and altogether commanded considerable admiration.

Fruit.—This was on rather a limited scale, but the quality in most cases was good. For the best Pine-apple, Mr. H. C. Letts, gr. to Earl Zetland, Upleatham, was 1st; Mr. Noble, of Darlington, 2d. Two bunches of white Grapes: Mr. Moulton 1st, Mr. James Mann 2d, Mr. Hutchinson 3d. Two bunches black Grapes: Mr. Hutchinson 1st, Mr. Simpson 2d, Mr. Mann 3d. Peaches and Nectarines were in limited quantities, but the prizes for fruit were not such as to command a large show.—In the amateurs' class there were some excellent plants shown, far above the average that we generally meet with.—A large circular tent was principally filled with miscellaneous collections from the trade, the one from Mr. B. S. Williams occupying the greater part of the centre, staged with some beautiful specimens of his new and rare plants, including *Croton Queen Victoria*, *Adiantum palmatum*, *Panax laciniatum*, and altogether the most choice and attractive group ever shown in Newcastle. Mr. Watson, Mr. Thompson, Mr. S. Nain, Mr. Charlton, Stewart & Mein, all exhibited large collections, which added very much to the interest of the show. (*From a Correspondent.*)

Obituary.

THE death is announced of Mr. PETER DRUMMOND, of the well-known firm of Messrs. William Drummond & Sons, seedsmen, Stirling. Mr. Drummond died at Edinburgh, at the age of seventy-eight.

- July 12.—A very fine warm day. Partly cloudy.
- 13.—A fine day, warm and cloudy. Few drops of rain at 11 P.M.
- 14.—Dull and showery, fine at times. Cool day.
- 15.—Generally fine, but frequently dull and showery.
- 16.—A dull miserable wet day. Cool. The rain fell very heavily at night.
- 17.—Overcast and dull till evening. Then fine. Clear at night. Rain fell in early morning, and from 5 to 7 P.M.
- 18.—A fine day. Partly cloudy. Cool.

LONDON: *Barometer*.—During the week ending Saturday, July 14, in the vicinity of London, the reading of the barometer at the level of the sea increased from 30.19 inches at the beginning of the week to 30.32 inches by the morning of the 9th, and steadily decreased to 29.29 inches by the end of the week. The mean reading for the week at sea level was 30 inches, being the same as that of the previous week, and 0.02 inch below the average.

Temperature.—The highest temperatures of the air observed by day ranged from 77° on the 10th to 60° on the 8th; the mean value for the week was 71°. The lowest temperatures of the air observed by night varied from 45° on the 8th to 59° on the 14th; the mean for the week was 52°. The mean daily range of temperature in the week was 19°, the least range to the day was 10°, on the 14th, and the greatest 24°, on the 10th.

The mean daily temperatures of the air and the departures from their respective averages were as follows:—8th, 51°.9, -10°.1; 9th, 57°.2, -4°.9; 10th, 63°.8, +1°.6; 11th, 61°.8, -0°.5; 12th, 62°.8, +0°.4; 13th, 62°.2, -0°.3; 14th, 62°.7, +0°.1. The mean temperature of the air for the week was 60°.3, being 2° below the average of sixty years' observations.

The highest readings of a thermometer with blackened bulb in vacuo, placed in sun's rays, were 151° on the 10th, 143° on the 12th, 139° on the 13th, and 127° on the 11th; on the 9th the reading did not rise above 106°. The lowest readings of a thermometer on grass, with its bulb exposed to the sky, were 35° on the 8th, 39° on the 9th, and 40° on the 13th; the mean of the seven low values was 43°.

Wind.—The direction of the wind was S. W., and its strength brisk. The weather during the week was for the most part fine and cool, though the sky was generally cloudy.

Rain fell on two days during the week; the amount collected was 0.40 inch.

ENGLAND: *Temperature*.—The highest temperatures of the air observed by day were 79° at Norwich, 77° at Cambridge, 77° at Blackheath, and 77° at Nottingham; at Liverpool and Bradford 66° was the highest temperature. The mean value from all stations was 72°. The lowest temperatures of the air observed by night were 40° at Nottingham, 42° at Bristol and Eccles, and 43° at Hull; at Liverpool 53° was the lowest temperature: the general mean from all stations was 45°. The range of temperature in the week was the greatest at Nottingham, 36°, and the least at Liverpool, 12°. The mean range of temperature from all stations was 27°.

The mean of the seven high day temperatures of the air was the highest at Cambridge, 73°, and the lowest at Liverpool and Bradford, both 63°;

the mean from all stations was 68°. The mean of the seven low night temperatures of the air was the lowest at Truro, 49°, and the highest at Liverpool, 55°; the mean value from all stations was 52°. The mean daily range of temperature in the week was the least at Liverpool, 8°, and the greatest at Cambridge, 22°; the mean daily range from all stations was 15°.

The mean temperature of the air for the week from all stations was 58°, being 3° lower than the value for the corresponding week in 1876. The highest value was 61°, at Norwich and Cambridge, and the lowest 56°, at Truro, Eccles, and Bradford.

Rain.—The amounts of rain measured at the several stations varied from 2¼ inches at Wolverhampton and Manchester (2 inches of which was measured on Saturday at each place), to one-tenth of an inch at Norwich and Bradford, at Portsmouth two-hundredths of an inch only was measured. The fall of rain on Saturday, July 14, at some places was very heavy, 1¼ inch fell at Liverpool, 1½ inch at Eccles, 1 inch at Sheffield, and eight-tenths of an inch at Brighton, Bristol, and Hull, whilst at Portsmouth, Bradford, Norwich and Sunderland no rain fell. The average fall over the country was nine-tenths of an inch nearly. The weather during the week was generally fine, though the sky was for the most part cloudy.

SCOTLAND: *Temperature*.—The highest temperatures of the air varied from 72° at Aberdeen to 62° at Greenock; the mean value from all stations was 67°. The lowest temperatures of the air ranged between 42° at Aberdeen and 49° at Edinburgh; the general mean from all stations was 45°. The mean range of temperature in the week from all stations was 21°.

The mean temperature of the air for the week from all stations was 57°, being 2° lower than the value for the corresponding week in 1876. The highest was 58°, at Edinburgh, Dundee, and Aberdeen, and the lowest 55°, at Paisley.

Rain.—The amounts of rain varied from 1½ inch at Greenock, 1¼ inch at Dundee, and 1 inch at Glasgow and Edinburgh, to one-quarter of an inch at Aberdeen; and the average fall over the country was nine-tenths of an inch.

DUBLIN.—The highest temperature of the air was 72°, the lowest 51°, the range 20°, the mean 60°, and the fall of rain 1¼ inch.

Erratum.—At p. 58, col. 2, July 14, in "Meteorological Observations for June," the mean amount of cloud should be 4.2.

JAMES GLAISIER.

Enquiries.

He that questioneth much shall learn much.—BACON.

195. The subjoined questions would be better referred to some local solicitor, but as some of our correspondents may be able to give their personal experience we print the questions. It will be seen that they refer to matters of great importance to horticulturists. Compliments frequently reach us as to the uncertainty of the law, or perhaps of its administration, and on all accounts it is most desirable that some authoritative settlement should be arrived at.—1. "Having purchased some land for a nursery and being now erecting greenhouses on it, I wish to know if they are not exempt from the supervision and control of the Local Board in the form and materials used in their construction, as they are away from other property? 2. Are not all horticultural erections considered stock-in-trade, and not rateable?" *J. W. Williams.*

196. ANTS.—Would some of your readers oblige me as to the best means of ridding a meadow of ants? The soil is clay, and I have dug them out every winter for years, but to very little purpose, as they seem as strong as ever. *A Constant Reader.*

APIARY: *M. A. J., Hendon.* You have adopted, perhaps unconsciously, the nadir system with your bees. It is difficult to state which hive the queen will have made her home, although she will probably in your case be discovered in the under hive. We should advise you to take the bottom hive away about the first week of August. First smoke them thoroughly with old fustian, then, without losing time, turn the bottom hive on the top of a pail; at the same time carefully lift the upper hive on the top of it, tying a tablecloth in the centre, so as to keep in the bees; then gently drum, or beat the under hive with both hands; in about a quarter of an hour the whole of the bees will have ascended to the old hive. This may now be lifted on the old stand. This operation of driving should be performed on a very fine and warm day about noon; if it is done carefully you will not sacrifice the life of a single bee, and you will also

be secure of the queen. If the old hive is worthless or decayed drive them into the lower hive; in this case you will find very little honey. If you find any difficulty write us again at once.

BOOKS: *T. G. H.* We know of no book specially devoted to the subject.

CUCUMBERS: *R. S. W. T.* The appearance is not like the disease, but is rather suggestive of debility. As they were growing so vigorously, possibly you have not kept up the feeding.

FUCHSIA: *C. Turner.* Mr. Bland's Champion of the World is an enormous flower, and evidently, from the foliage, of vigorous growth also. The leaves sent were 4 inches long by 2½ inches broad; and the flower (red and purple, double) 3 inches across the expanded sepals, which are over ¼ inch broad, and 2½ inches across the densely double corolla. For a conservatory, where it could be grown to large size, it would be a telling variety, but is too coarse for pot-culture.

GRAPES: *Subscriber.* The berries are badly scalded; the sun must have caught them damp, or else they have been deprived of the shade of the foliage. The variety is very objection to this affection.

INSECTS: *A Sufferer.* The leaves are being devoured or skeletonised by the Rose-leaf Saw-fly. You can do nothing but pick them off and burn them, or kill them between the finger and thumb.—*J. Mullings.* Cricocis Asparagi, the Asparagus beetle. It belongs, as your intelligent correspondent surmises, to the same family as the Colorado beetle. No cure known on the small scale except careful hand-picking and knocking off the larvæ into an open umbrella held reversed below them, and then destroying those that are taken. *A. M.—J. Webster.* The Lime-leaf nail-gall produced by a small mite called Phylloxera vitarum. Not common. *A. M.—A Subscriber, Reading,* sends us three beetles, which were found clinging to the inside of a barrel received from New York last April, and which he thinks may "probably be a species of Colorado beetle." They are no such thing—only common black beetles!—*C. B.* This is the Pear tree slug (Tenthredo amburata)—a saw-fly that does considerable mischief to the fruit by destroying the cuticle and parenchyma of the upper surface of the leaf whenever it is present in large numbers. *A. M.*

INSECT IN BEE-HOUSE: *A. F.* Osmia parietina—a wild bee whose nest is often found in locks and other out-of-way places. It does no harm to hives so far as we know. *A. M.*

INSECT IN GINGER: *W. T.* The small borer has done all the mischief. Its name is Nyltetius pectinicornis. More next week. *A. M.*

JASMINE: *Cam.* It appears to be the variety of the white Jasmine sometimes called grandiflorum, which is we believe the same as Jasminum affine. We were not aware that it produced double flowers, and would recommend you to propagate some of the shoots which do so, and see if this quality is constant, or merely the result of the very "free" growth you mention.

LANDSCAPE GARDENER: *Agricola.* Read the works of Kemp, Repton, and Loudon, and place yourself under some one who stands high in the profession. The practical part can only be learned by experience, and the principles by well directed study.

MEALY-BUG IN CONSERVATORY: *W. R. B.* We have no experience to warrant us in recommending carbolic acid. As the house is to be cleared and the creepers all cut back well, we should recommend before painting and whitewashing to thoroughly wash and scrape the walls and roof, using soft-soap dissolved in water, and applied as hot as possible—boiling hot—from a garden engine after washing, if practicable. Then we would remove the whole of the surface soil to the depth of 2 or 3 inches and renew it, or if paved all over the scrubbing and scalding process should be fully carried out on the floor also. Of course all cavities and crevices on the wall or woodwork should be closely stopped with mortar and putty respectively before applying the whitewash or paint. So much for the house. The stems of the creepers so far as retained should be thoroughly washed with soap and water, and the plants set outdoors—no doubt infested more or less—should be looked over, cleaned, and well washed with the engine two or three times before they are returned to the house.

MILDEW: *W. D. F.* You do well in dusting the leaves and fruit with flowers of sulphur. The easiest way of applying it is through a muslin bag. You must be very careful not to put too much sulphur on the pipes, or make them too hot, or the result will be a serious loss of foliage. Try Speed's Mildew Annihilator. It is sold in bottles, and has been highly spoken of.

MIMULUS: *Mimulus.* The specimens were too imperfect to judge; it seems to have some of the features of *M. roseus*, but as a seedling it may be distinct in habit, and eventually prove to be worth introducing to general cultivation.

NAMES OF PLANTS: *Dick Radcliffe & Co.* An umbelliferous plant, which we cannot name without flowers and fruit.—*Agricola.* 1, Cynosurus cristatus; 2, Poa trivialis; 3, Festuca ovina.—*W. Hopwood.* Clethra arborea.—*Duncan Munro.* Melia Azadirachta.—*E. W. N.* Pyrola rotundifolia, nat. ord. Ericaceae.—*Z. Y. X.* Campanula persicifolia.—*A. G.* Vanda testacea, Rehb., Acridis testaceum of Lindley.—*C. A.* Dendrobium chrysanthemum.—*J. C. K.* Saccobolium gurgulium, very near *S. guttatum*.—*A. J. N.* There are too many garden varieties of *Coleus* for us to undertake to name any of them, and especially from leaves only.—*W. D. F.* We cannot find any indication of their having been received.—*A. B.* Lastrea æmula.

PELAGONIUMS: *J. George.* Your flowers had sadly fallen to pieces. *St. George* (Ivy-leaved) is, however

a decided advance on any we have seen yet in size of flower and in form; it is a bright rose-pink. The other Ivy-leaved sorts are less striking. General Grant, a scarlet zonal, is all that can be desired, so far as the quality of the flower and truss are concerned.

PHYLOXERA: C. H. The specimens were hardly sufficient to decide with certainty, but we fear the worst. Please send some more roots, and pack them so that they will not get dry before reaching us.

STRAWBERRIES: G. C. Short. The box and its contents were completely smashed.

TOUTING FOR SITUATIONS: R. S. The practice you mention is decidedly very bad.

TREES: VARIOUS: G. M. 1, yes, but not advisable; 2, apply to Messrs. Barron & Son, the Elvaston Nurseries, Borrowash; 3, the flowers are red, and produced in the autumn. It grows to a moderate sized tree.

VINE-LEAVES SPOTTED: A. M. P. We should regard the yellow spotting as a sign of debility, so that your suggestion, that the borders are in a bad condition, is probably correct. We do not detect any insect or fungus.

VINE MILDEW: Constant Reader. Try Speed's Mildew Annihilator.

WHITE PLUM LEAVES: Diss. Generally considered due to excess of bloom; but we are not satisfied with the correctness of the explanation.

FOREIGN SUBSCRIBERS sending Post-office Orders are requested to make them payable at the post-office, King Street, Covent Garden, London, and at the same time to inform the Publisher at the office of this Journal.

Correspondents are specially requested to address, post-paid, all communications intended for publication to the "Editors," and not to any member of the staff personally. The Editors would also be obliged by such communications being sent as early in the week as possible. Correspondents sending newspapers should be careful to mark the paragraphs they wish us to see. Letters relating to Advertisements, or to the supply of the Paper, should be addressed to the Publisher, and not to the Editors.

COMMUNICATIONS RECEIVED.—A. A. (thanks).—C. W. S.—W. S.—A. W.—P. L. S.—J. F. R.—A. S. K.—J. H.

Markets.

COVENT GARDEN, July 19.

Cherries are still arriving in bad condition, and are only cleared at very low prices. Currants have improved, and Raspberries continue to make ready sales at high rates. Owing to the London season being nearly over, the demand for high-class fruits has considerably decreased, and we may look forward to a steady fall in such goods as Peaches, Grapes, Melons, &c. James Webber, Wholesale Apple Market.

CUT FLOWERS.

Table with 2 columns: Item and Price. Includes Bouvardias, Carnations, Cornflower, Eschscholtzia, Eucharis, Gardenia, Heartsease, Heliotropes, Lilies, Mignonette, Myosotis.

PLANTS IN POTS.

Table with 2 columns: Item and Price. Includes Balsams, Bedding-out plants, Begonias, Bouvardias, Calceolaria, Clematis, Clockscombs, Coleus, Cyperus, Dracena terminalis, Ferns, Papyrus, Fuchsias, Heaths, Heliotropes, Hydrangea, Lilioms in var., Mignonette, Myrtles, Palms in variety, Pelargoniums, Petunias, Rhodanthe, Roses, Valotta purpur.

VEGETABLES.

Table with 2 columns: Item and Price. Includes Artichokes, Aubergines, Beans, Beet, Cabbages, Carrots, Cauliflowers, Celery, Chilis, Cucumbers, Endive, Garlic, Gooseberries, Herbs, Horse Radish, Leeks, Lettuce, Mint, Onions, Parsley, Peas, Radishes, Spinach, Tomatoes, Turnips, Vegetable Marrows.

FRUIT.

Table with 2 columns: Item and Price. Includes Apricots, Cherries, Grapes, Lemons, Melons, Oranges, Peaches, Pears, Pine-apples, Strawberries, Figs.

SEEDS.

LONDON: July 18.—Rather more activity is now seen in the agricultural seed trade, the recent genial and welcome rains having greatly stimulated the demand for field Rape and Mustard seeds. Several parcels of new English Trifolium have this week arrived at market: this year our home-grown seed has the start of the French. A noticeable feature of the market to-day was some speculative business in yearling Trefoils at a considerable advance on late currencies. One or two samples of new English Trefoil Cosh have already put in an appearance on Mark Lane. As previously noted, the prospects of the new Trefoil crop are uniformly unfavourable, both at home and abroad. In red Clover seed there is no business at present doing. Foreign Italian will, it is said, be plentiful; and, consequently, low offers are being made from France. In bird seeds there is no variation of importance. For the few blue Peas remaining, former terms are readily obtained. Feeding Linseed tends upwards. John Shaw & Sons, Seed Merchants, 37, Mark Lane, London, E.C.

CORN.

At Mark Lane on Monday trade was firm. The prices demanded for Wheat, both English and foreign, were 2s. above those of a week back, but millers were not anxious buyers, and the improvement was not in all cases submitted to. For Barley an advance of 1s. per quarter asked upon grinding qualities was not readily given. Malt remained as before. For Oats prices were the turn better, except as regards Archangel. Maize was fully as dear; while Beans, Peas, and flour were quiet at late rates.—The tone of the market on Wednesday was hardly so good as on Monday, owing to the more settled weather. The holders of Wheat, however, were not anxious sellers, and notwithstanding the limited business doing the advanced prices of Monday were supported. Barley was rather dull, and of Oats, of which there was a good supply, the trade was disappointing. Maize was pretty firm; and as regards Beans, Peas, and flour no change was reported.—Average prices of corn for the week ending July 14:—Wheat, 62s. 3d.; Barley, 34s. 7d.; Oats, 28s. 10d. For the corresponding week last year:—Wheat, 48s. 5d.; Barley, 32s. 3d.; Oats, 30s. 1d.

CATTLE.

At the Metropolitan Market on Monday there was a demand for beasts, and prices were not lower, choice qualities meeting a very ready sale. Sheep and lambs were plentiful, but trade was dull for them. The top quotations are quite the extreme for choicest descriptions. There were very few calves on offer, and trade was unaltered. Quotations:—Beasts, 4s. 6d. to 5s. 2d., and 5s. 8d. to 6s. 2d.; calves, 5s. to 6s. 4d.; sheep, 5s. to 5s. 6d., and 5s. 10d. to 6s. 1d.; lambs, 7s. to 7s. 10d.; pigs, 4s. 4d. to 5s. 4d.—On Thursday prime small stock sold at about Monday's prices, but inferior was drooping. For sheep the trade was rather healthier, and the best breeds a shade dearer. Lambs were quiet but steady, and calves sold at about late rates.

HAY.

The Whitechapel report for Tuesday states that there was a steady trade for fodder at the following prices:—Prime Clover, 100s. to 140s.; inferior, 85s. to 95s.; prime meadow hay, 90s. to 124s.; inferior, 70s. to 85s.; and straw, 44s. to 60s. per load. The supply was moderate.—On Thursday there was a fair supply of hay and straw on sale; trade was moderate, and prices steady. Quotations:—Clover, best, 100s. to 140s.; inferior, 85s. to 95s.; hay, best, 90s. to 124s.; inferior, 70s. to 85s.; and straw, 44s. to 60s. per load.—Cumberland Market quotations:—Superior old meadow hay, 128s. to 135s.; inferior, 105s. to 114s.; new hay, 90s. to 105s.; superior old Clover, 132s. to 140s.; inferior, 105s. to 118s.; new Clover, 90s. to 110s.; and straw, 57s. to 60s. per load.

POTATOS.

The Borough and Spitalfields markets reports state that, with arrivals on a moderately extensive scale, the trade continues steady, at the following prices:—Jersey, round, 200s. to 220s.; ditto, kidneys, 210s. to 240s.; Cherbourg, round, 200s. to 210s.; ditto, kidneys, 190s. to 220s.; Essex kidneys, 200s.; Kent kidneys, 260s.; Essex shaws, 190s. to 210s.; Kent shaws, 200s. to 230s.; Dutch Potatoes, 3s. 6d. to 4s. 6d. per basket.—The imports into London last week consisted of 988 baskets 200 bags from Rotterdam, 776 cases 302 boxes from Cherbourg, 434 barrels 148 tons from Dunkirk, 123 baskets 41 packages from Antwerp, 516 boxes from Palermo, 495 boxes from Barfleur, 276 cases from St. Vaast, 73 barrels from Hamburg, 77 baskets from Havre, 58 from St. Nazaire, 26 from Malta, and 35 packages from Naples.

COALS.

Business at market during the week was steady at previous prices, the only rise being in Hartleys, which advanced 6d. Quotations:—Ebeside West Hartley, 17s. 3d.; Walls End—Haswell, 19s.; Hutton, 19s.; Lambton, 18s. 6d.; Seaton, 15s. 3d.; East Hartlepool, 18s. 9d.; Thorpe, 16s. 6d.

Sole Medallists for the Best Hot-Water Apparatus at the United States Centennial International Exhibition, Philadelphia.

By Her Majesty's Royal Letters Patent

WRIGHT'S ENDLESS-FLAME-IMPACT HOT-WATER BOILERS.

GUARANTEED The most Powerful, the most Rapid, the most Economical, the Simplest, and the Cheapest in the World.

"The 'Boiler of the Future.' I have no doubt about this."—WM. THOMSON, Tweed Vineyards.

From the "Gardener," July, 1877. WRIGHT'S PATENT ENDLESS FLAME-IMPACT BOILERS.

"The first intimation I had of the existence of these boilers, or of their inventor, was a pamphlet I received through the post. Its perusal satisfied me that Mr. Wright had a sounder theoretical knowledge of the subject of heating water than any author I had ever perused. I also liked the construction of his boiler better than any I had previously met with. Mr. Lewin, gardener, Drumpeller, was represented as having fixed one of these boilers, and as bearing testimony to its excellence; and as I knew Mr. Lewin to be not only a good gardener, but a shrewd, clever man, I felt satisfied that the boiler must be of the excellence which my own knowledge of such matters led me to conclude it was from its construction.

"Having occasion to be in the neighbourhood of Glasgow last February, I went to Airdrie and called on Mr. Wright, who took me to the foundry in Glasgow where the boilers are manufactured. There he put one together in a few minutes, and a closer examination of it only strengthened my preference for it over all boilers I had previously seen. I ordered a 4-0 boiler, which I have fixed to heat 2000 feet of 1-inch pipe in two early vineeries. One, a Muscat-house, 200 feet long and 16 feet wide, is built and planted, the other will not be built till autumn; so that at present the boiler is only heating 1300 feet of pipe, which it does with a very small fire and the damper nearly close in, burning little more than half the coal used in any other boiler I have—and I have some of the most approved, both of my own and other people's designs.

"The result of the trial I have had of Wright's boiler is, that I have ordered four more, and will pull out all my other boilers as opportunity occurs, and replace them by his, with a view both of saving and efficiency.

"No doubt many will ask wherein consists the cause of the efficiency of this boiler over others? To explain this, it may be well to observe that when fresh coal is added to the fire of any other boiler known to the writer, the first process that goes on is the distillation of the gas from the new coal, and its rapid discharge, in advance of the flame, up the chimney and uncombusted. This is not only a great evil in itself, but to effect it the heat is extracted from the fire that was in the furnace when the fresh coal was added, and little or no benefit is got from the fire till the gas is up the chimney and the destruction of the carbon in the coal has begun.

"Many expedients have been adopted to prevent this loss; and no doubt careful stoking can do much in the case of large boilers for generating steam, where there is a long fire, and where the fresh coal is always added to the front of the fire, compelling the gas to pass over the red fire and get ignited; but in the case of boilers used for heating hot-houses, this is not practicable, and especially with ever-changing stokers, who, as a rule, think if they throw a given quantity of coal on the fire no further care is needed. Now, in the case of Wright's boilers, distillation of gas takes place as in others, but it has no possible chance of escape uncombusted—for gas and flame are compelled to meet face to face, over and over again, ere they leave the boiler; consequently all the gas is consumed, and the heat from it made to impinge directly on the flat surfaces of the various sections of the boiler on its way upwards. Here lies the great secret of this boiler's power.

"What also adds not a little to increase the power of the boiler is the method adopted for supplying a hot-blast, by passing air from the front of the cast-iron stand on which the boiler is placed through an intricate passage, till it is discharged at the back of the ash-pit under the bars. This leads to the most perfect combustion of the commonest cross-coal. There is also an arrangement by which a hot-blast is thrown into the furnace through the furnace door. Then there is a moderate supply of air entering the furnace all round, where the first section is laid on a hester-jack of the boiler; this has the same effect on the fire as the well-known Argand burner has on the lamp, giving a clear fierce flame. These boilers are made up of a series of simple castings, jointed by means of india-rubber rings, which allow them to expand and contract; therefore they are sure to be the safest of boilers."

"WM. THOMSON. Tweed Vineyard, June 14, 1877."

"I think yours the most perfect 'Heat Trap' yet invented."—DAVID THOMSON, Drumlaigh Gardens."

For details and particulars as to the various sizes made, and prices, please see our pamphlet, entitled, "OUR BOILERS AND HEATING," which will be handed to all applicants, post-free.

We are prepared to supply Thirty Different Boilers of all powers, sizes, and heights, and can vary these to suit any particular situation or requirement.

In consequence of the increasing demand for Conservatories, in which pure art is combined with moderate cost, T. H. P. DENNIS & Co. have been led to introduce designs of a character hitherto unknown. One of these designs, showing a house 22 feet 6 inches x 13 feet 6 inches, is annexed, and the result, as regards the extremely low price (which includes fixing, glazing, painting, carriage, &c.), has been attained only by special machinery and a system of interchangeable parts.

T. H. P. DENNIS & Co. are also prepared to provide and fix Hot-water Heating Apparatus and Horticultural Buildings of any dimension or description.

Full-sized specimens of Greenhouses, &c., and Hot-water Apparatus in work, can be inspected at Mansion House Buildings, London, E.C.

Gentlemen waited upon at their residences by experienced designers.

Estimates and Plans free.

PAXTON'S CALENDAR.

Now Ready, a New and thoroughly Revised Edition of the

COTTAGER'S CALENDAR OF GARDEN OPERATIONS.

ORIGINALLY COMPILED BY THE LATE SIR JOSEPH PAXTON, M.P.

OPINIONS OF THE PRESS.

"It has been carefully revised by an experienced gardener, and the lists of vegetables, fruit, and flowers have been corrected by the substitution of the most approved modern kinds, in place of those which were mentioned in the first edition, and many of which have ceased to be worthy of cultivation. It is a thoroughly sound, practical treatise; but it has been so long before the public, and so deservedly appreciated, that any special commendation of it now is unnecessary."—*Midland Counties Herald.*

"This is a handy volume, consisting of seventy pages of letterpress and illustration, containing much and varied information likely to prove useful to all cottagers, &c., who possess a garden. To all such, who require a cheap and reliable book of reference, we heartily recommend it."—*Lloyd's.*

"We are quite glad to see this useful little book once more, and it is like a whiff of perfume from the heather in bloom to read on the wrapper 'two hundred and twenty-first thousand.' We advise all who are interested in the promotion of cottage gardening to sow this little book broadcast."—*Gardener's Magazine.*

"The information conveyed in this little book is well adapted for all persons having small plots of ground. The necessary operations for each month are clearly laid down, and are of a thoroughly practical nature. The sorts of both fruit and vegetables are well selected, many of them being excellent in quality. To our readers who are interested in the cultivation of their flower and kitchen gardens, we can safely recommend this as being a most concise and useful work."—*Bell's Messenger.*

Specially adapted for Pumping in Gentlemen's Houses and Grounds. No Labor Required.

HAYWARD TYLER & Co.,
 84, WHITECROSS STREET, LONDON.

CRITCHLEY'S PATENT HEAT REGULATOR, AN APPARATUS FOR REGULATING THE HEAT IN HORTICULTURAL BUILDINGS.

A, Iron Box fitted up water-tight. B, Pipe or Supply of Water from Boiler. C, D, Pipes for Circulating Hot-Water. E, F, Pipes for Return of Water to Iron Box. G, Pipe for Returning Water to Boiler. H, I, J, K, Piston-Rods for Opening and Closing Valves.
 The advantages of these Regulators are that houses may be kept at different degrees of heat, or the circulation of water and heat entirely stopped in one part and not in others. They may be fitted with as many valves as required, and are particularly adapted for forcing houses where top and bottom heat is used. They may be fixed in any part of the apparatus most suitable for working, without regard to the position of the Boiler.

The following Testimonial has been received:—
 "Derkeley Castle, April 13, 1875.
 "Gentlemen, — I am happy to inform you, now that the late severe winter is past, that the Hot-Water Apparatus erected by you does its work to my entire satisfaction. As to the two Heat Regulators, which represent thirty valves, I have had ample opportunities of practically proving them, and unhesitatingly admit they are far superior to any other valve in fact, I think it the greatest improvement that has come out for horticultural purposes.
 "I am, Gentlemen, yours truly,
 "R. H. CRONK,
 "Gardener to the Right Hon. Lord Fitzhardinge."
 Estimates and Plans furnished for Warming Gentlemen's Mansions and Public Buildings. Orders attended to in any part of the kingdom, and guaranteed to answer their intended purposes. Prospectus and Price Lists post-free.

LUDGATE HILL, LONDON, E.C.

And 21, BACHELOR'S WALK, DUBLIN.

No AGENTS.

Oil Paint No Longsr Necessary.

HILL AND SMITH'S BLACK VARNISH for Preserving Ironwork, Wood, or Stone. This Varnish is an excellent substitute for oil paint on all outdoor work, while it is fully two-thirds cheaper. It was introduced upwards of thirty years ago by the advertisers, and its genuine good quality, notwithstanding a host of unprincipled imitators, is fully attested by its constantly increasing sale. It may be applied by an ordinary labourer, requires no mixing or thinning, and is used cold. It is used in the grounds at Windsor Castle, Kew Gardens, and at the seats of many hundreds of the Nobility and Gentry, from whom the most flattering testimonials have been received, which HILL & SMITH will forward on application.

Sold in casks of about 30 gallons each, at 1s. 6d. per gallon, at the Manufactory; or 1s. 8d. per gallon carriage paid to any Station in the Kingdom.

UNSOLICITED TESTIMONIAL RECEIVED MAY 3, 1877.
"The Rylands, Alderly Edge, Manchester.—Messrs. Hill & Smith.—Sirs.—For some 20 years, I have used your 'Black Varnish,' and shall be glad if you will forward me another cask, as I consider it the best thing known for the preservation of all outdoor work, either wood or iron, that requires to be painted.
—Yours respectfully, ALFRED LOWE, J.P."
Apply to HILL and SMITH, Brierley Hill Ironworks, near Dudley; and 113, Queen Victoria Street, London, E.C., from whom only it can be obtained.

CUTION.—It having lately come to the knowledge of HILL & SMITH that spurious imitations of this Varnish are being offered by unprincipled dealers at a slight reduction in price, they would especially draw attention to the fact that every cask of their Varnish is legibly marked with their name and address, without which none is genuine.

GREEN'S PATENT "SILENS MESSOR,"

Or Noiseless Lawn-mowing, Rolling, and Collecting Machines for 1877.

The Winner of every Prize in all cases of competition.

The superiority of these Machines over those of all other makers is universally acknowledged. They will Cut either long or short Grass, Bents, &c., wet or dry.

These advantages no other Lawn Mowers possess.

They are the simplest in construction, the easiest to work, the least liable to get out of order, make little noise when in use, and are the most durable Lawn Mowers extant.

The largest stock of Mowers kept in London is to be found at our Establishment, 54 and 55, Blackfriars Road, where purchasers can select from upwards of 500 machines of hand, pony, and horse power, and have their orders executed the same day they are received.

Every Lawn Mower sent out is guaranteed to give entire satisfaction, otherwise it may be returned at once free of cost to the Purchaser.

N.B.—Those who have Lawn Mowers to repair will do well to send them either to our Leeds or London Establishment, where they will have prompt attention, as an Efficient Staff of Workmen is kept at both places.

Descriptive Illustrated Price List free on application.

ADAMS and FRANCIS INSERT

ADVERTISEMENTS in all Newspapers, Magazines, and Periodicals. List of London Papers on application. ADAMS and FRANCIS, Advertisement Agents, 59, Fleet Street, E.C.

ADVERTISERS are requested to note that although we do not object to receive Letters to be called for, we cannot undertake to forward them.

WANTED, a PARTNER for the Nursery and Vegetable Business. One who thoroughly understands Seed and Floral in all its branches.—F. PENNINGTON, The Nurseries, Newton-le-Willows, Lancashire.

PARTNERSHIP.—A Nurseryman, carrying on a successful business within 25 miles of London, is desirous of meeting with a Partner. Failing health causes Advertiser to wish to find a man, or men who in, say, one or two years would be able to take over from him the entire business. Money would be required, but every facility be afforded provided substantial guarantees were given. The fullest references given and required.—Address, by letter, giving outline of means and position, NURSERMAN Messrs. Norris, Allens & Carter, Solicitors, 20, Bedford Row, London, W.C.

WANTED, a Gentleman of experience to undertake the Management of a Decorative Flower and Fruit Show at the Agricultural Hall, London.—Apply, by letter, giving terms, &c., to J. H. RAFFETY, Agricultural Hall, London, N.

WANTED, a HEAD WORKING GARDENER, where one other and a Boy are kept to assist. He must thoroughly understand the profession. No one need apply who cannot produce satisfactory testimonials as to character and competency.—Apply, stating wages expected (to live in the Lodge), to G. INGLIS JONES, Maidene Park, near Newport, Monmouthshire.

WANTED, a steady single Man as GARDENER, to go out at Jobbing Work. Comfortable and constant place. No time lost. Over-time paid for. State age and wages required.—G. W., 15, Craven Cottages, Hammersmith, W.

WANTED, a GARDENER who thoroughly understands Orchids, to take charge of Garden and Orchard-house. Wages 25s. per week and milk.—Apply at St. Stephens, Amand Park Road, Twickenham, S.W.

WANTED, a SINGLE-HANDED GARDENER, on August 4. State wages required.—Apply, by letter only, to G. B. S., Mr. Way, 21, Wellington Street, Strand, W.C.

WANTED, IMMEDIATELY, an active and industrious young Man as SECOND GARDENER, with a fair knowledge of Plants under Glass, Flower and Kitchen Gardening. Wages, 20s. per week. Also a THIRD HAND, well used to Garden Work. Wages, 15s. per week.—State age and references to W. G. HAZELL, The Gardens, Caterham Court, Surrey.

WANTED, an active, steady Man, of good address, as GROUND FOREMAN; must be well up to the Value and Culture of Trees, Shrubs, Evergreens, and Conifers especially. A man without family preferred. Wages, 30s. per week and house. Also a young Man as an ASSISTANT PROPAGATOR, in the Houses. Wages, 21s. per week, to begin with.—Apply, with full particulars in each case, to JOHN SHAW and CO., Stamford Nursery, Bowdon, Cheshire.

Outdoor Foreman.

WANTED, an active, intelligent, sober, single MAN, well up in the Culture and Propagation of Ornamental Trees, Shrubs, Rhododendrons, Roses, &c.—R. P. KER and SON, Aigburth Nursery, Grassendale, Liverpool.

WANTED, a respectable Young MAN for the Houses in a Nursery, where Plants are grown for Market. One who thoroughly understands his duties, and in whom confidence could be placed, will find this a good opportunity.—State wages, age, and abilities, &c., to Mr. J. BOWLEY, Hedley House Nursery, Notts.

WANTED, two strong young MEN for the Flower and Kitchen Garden. Wages 16s. per week.—Apply to THE GARDENER, Wickham Court, Beckenham, Kent.

WANTED, a steady MAN, accustomed to Garden Work and to take Charge of Poultry and Cattle, and make himself generally useful. A furnished room found.—State age and wages required, and address M., Faulkner's, Waterloo Station, W.C.

WANTED, IMMEDIATELY, a strong LAD, accustomed to work in the Houses.—The Nursery, 30, High Street, Clapham, S.W.

WANTED, a GARDEN BOY.—Apply, by letter, to Mr. CROUCHER, Sudbury House, Hammersmith, W.

WANTED, a useful handy MAN, to keep in repair the Glass Erections, Outbuildings, Fences, &c.—Apply, stating age, wages expected, and with reference, to HENRY POTTER, Mid-Surrey Nurseries, adjoining the Railway Station, Sutton, Surrey.

WANTED, a good and ready CORRESPONDING CLERK, who would have occasionally to Travel; good address and an extensive knowledge of Plants and General Gardening, as well as Nursery Work, indispensable. Salary, £100 per annum, with a prospective increase. State requirements and services, in own handwriting, to "HORT.", 46, Escher Street, Kennington Lane, S.E.

WANTED, an experienced CLERK, who has been accustomed to the Nursery or Seed Business. Salary to commence at £100.—B., Barr & Sugden, 12, King Street, Covent Garden, W.C.

WANTED, as SHOPMAN and occasional TRAVELLER, a thoroughly experienced, energetic Man; married. Unexceptionable references required as to ability, &c.—Apply, stating age, salary required, and all other particulars, to X. Y. Z., Messrs. Hurst & Son, 6, Leadenhall Street, London, E.C.

WANTED, a SECOND SHOPMAN; married; must be industrious, energetic, well up to the trade, and of good address.—Apply, with all particulars, to ALPHA, Messrs. Hurst & Son, 6, Leadenhall Street, E.C.

WANTED, an intelligent, respectable young MAN, with some experience, in a small Retail Shop, and to make out Invoices, &c.—State age, reference, and wages, to JAMES BIRD, Nurseryman, Downham.

WANTED, an active Young MAN, thoroughly trained, and with good references.—Apply, stating particulars of experience and salary expected, to W. A., Mr. R. Cooper, 152, Fleet Street, London, E.C.

WANT PLACES.

E. G. HENDERSON

AND SON have many excellent GARDENERS with approved testimonials for ability now waiting in their Nurseries for re-engagement.

E. G. H. & Son will be pleased to answer any enquiries from Noblemen and Gentlemen requiring such.—Pine-apple Nursery, Maida Vale, London, W.

B. S. WILLIAMS, having at the present time several very excellent GARDENERS upon his Register, is desirous of placing them in Situations where great experience and trust are required. B. S. W. would at the same time beg to intimate that when a Gardener is applied for that the filling of the situation should be left with him, as that would prevent unnecessary correspondence and delay.—Victoria and Paradise Nurseries, Upper Holloway, London, N.

Head Gardeners.

JOHN LAING AND CO. can at present recommend with every confidence several energetic and practical Men, of tested ability and first-rate character. Ladies and Gentlemen in WANT of GARDENERS and BAILIFFS, or GARDENERS for First-rate Establishments or Single-hand Situations, can be suited, and have full particulars by applying at Stanstead Park and Rutland Park Nurseries, Forest Hill, London, S.E.

KINAHAN'S LL WHISKY. Universally recommended by the Medical Profession. A pure old spirit, mild, mellow, delicious, and most wholesome. Dr. Hassall says, "The samples were soft and mellow to the taste, aromatic and ethereal to the smell. The Whisky must be pronounced to be pure, well-matured, and of very excellent quality."—Wholesale: 20, Great Titchfield Street, London, W.

DINNEFORD'S FLUID MAGNESIA. The best remedy for ACIDITY of the STOMACH, HEARTBURN, HEADACHE, GOUT, and INDIGESTION; and the safest aperient for delicate Constitutions, Ladies, Children, and Infants. **DINNEFORD AND CO.**, 172, New Bond Street, London, and all Chemists.

HOLLOWAY'S PILLS.—Weak and Debilitated Constitution.—The present weather is trying to the robust; to the weak and debilitated it is overpowering. **HOLLOWAY'S PILLS** have long been noted for their Corrective and Purifying Powers, and are the Ready Restoratives of Health and Vigour. They Remove all Impurities from the Blood, Improve the Digestion, and Rouse the Liver, without interrupting pleasure, business, or study. **HOLLOWAY'S PILLS** Cool the System, Regulate the Circulation, Moderate Excessive Perspiration, Guard the Constitution in Critical Moments, and Save it from Destruction; in fact, so build up and Remove Failing Health as to make them the most desirable medicine. They neither Grip nor act violently or inconveniently on the most Delicate Bowels, and may, therefore, be taken by the Aged or Infirm, and safely Administered in the Nursery.

HENRY ORMSON,

THE WHITEHALL REVIEW:

A Journal of Information, Politics, Finance, Literature, and Society.

PORTRAITS IN CRAYONS.

From the "Morning Post," May 28, 1877.

"One of the most conspicuous successes in modern journalism has been achieved by our weekly contemporary, *The Whitehall Review*. The Editor has combined political intelligence and clever comment with social news and an amusing account of current fashionable gossip. To these attractions has been added the novel experiment of instituting a weekly issue of ladies' portraits. The essay was delicate, but it has succeeded beyond expectation."

On view the morning of Sale, and Catalogues had. On WEDNESDAY, August 1, 1877, in the Town Hall of Bruges, Belgium, between the hours of 11 A.M. and 6 P.M.,

A PUBLIC SALE

OF A RICH COLLECTION OF

Cycads, Araucarias, Phormiums, LAURELS, and PALM TREES,

Some Specimens of which are unique in Europe.

Public Exhibition on Tuesday, July 31.

A CATALOGUE to be had on applying to M. DU MON DE MENTEN, Quai long, 56, Bruges.

FOR SALE, a NURSERY BUSINESS, in an important town, South Coast. The premises are well adapted, and at present command a large trade, which daily increases. There are six hothouses and forcing pits. Rent £40. Lease 18 years. Price low.—Full particulars of Mr. JOHN J. DEVERELL, Auctioneer, 70, Kentish Town Road, N.W.

FOR IMMEDIATE DISPOSAL, a FLORIST and JOBBING GARDENING BUSINESS, capital commanding corner, good open thoroughfare. Excellent opportunity for a persevering Man. No risk. Connection, Business, and Goodwill complete. No reasonable offer refused, as Advertiser is going abroad. Communications will be answered. C. BUSBY, Florist, 85, Westbourne Park Road, Bayswater, W.

To Florists.—Sevenoaks, Kent.

TO BE LET, with Immediate Possession, in consequence of the failure of health, the GROUNDS, PREMISES, and BUSINESS of a FLORIST. Apply to J. VOLLER, Sevenoaks.

TO BE LET, a small NURSERY, in one of the pleasantest suburbs of London. Good frontage to the main road. Established sixteen years. Rent low. A good opportunity. For particulars apply to A. B., Post-office, Spring Grove, Isleworth, W.

TO BE LET, at Ferring, FLORENCE VILLA, together with Coach-house, Stable, &c., and large productive GARDEN of about 3 Acres, inclosed by a 7 feet wall, with about 18 choice Fruit Trees, comprising Nectarine, Apricot, Peach, Green Gage, Cherry, &c.: 450 Standard Fruit Trees, and a good Vinery, with eight vigorous Vines. The Land, at present used as a Market Garden, is generally very well arranged with Asparagus, Sea-kale beds, &c. The property is situated near the Goring and Angmering Railway Stations, and 4 miles from Worthing. For view of the Premises apply to Mr. ELSEY, the present occupier, and for further particulars to Mr. HENTY, The Grange, Ferring, near Worthing, Sussex.

FOR SALE, at Oundle, Northamptonshire, a LEAN-TO GREENHOUSE, 28 feet 6 inches long, by 16 feet wide, 13 feet high at back, and 7 feet in front. Ends and front partly brick and partly glass. Hanging Lights in front 3 feet 6 inches deep. For price and further particulars apply to J. W. SMITH, Esq., Oundle; or to see the same to EDWARD DUNCOMBE, New Street, Oundle. Oundle is on the Peterborough branch of the London and North-Western Railway.

Fibrous Peat for Orchids, &c.

BROWN FIBROUS PEAT, best quality for Orchids, Stove Plants, &c., £6 6s. per truck. BLACK FIBROUS PEAT, for Rhododendrons, Azaleas, Heaths, American Plant Beds, 17s. per ton. Delivered on rail at Blackwater, S. E. R., or Farnborough, S. W. R., by the truck-load. Sample sack, 5s. 6d. each. Fresh SPHAGNUM, 10s. 6d. per sack. WALKER and CO., Farnborough Station, Hants.

SCOTT'S WASP DESTROYER.—The only preparation made for thoroughly destroying Wasps, large Flies, &c. Sold in bottles, at 1s. 6d., 2s. 6d. and 5s. each. The larger sizes are the cheapest. May be obtained through any Seedsman, or direct from JOHN SCOTT, The Royal Seed Stores, Veovil.

SIMPSON'S RED SPIDER, THRIPS, &c., ANTIDOTE. Testimonials of the highest order on application. Per quart, condensed, 6s.; per pint, 3s. 6d. Supplied to Seedsmen and Chemists. Strongly recommended in the Gardener, and by many first-class Gardeners. Prepared by JOHN KILNER, Wortley, near Sheffield.

GISHURST COMPOUND.—Used by many of the leading Gardeners since 1850, against Red Spider, Mildew, Thrips, Greenfly, and other Blight in solutions of from 1 to 2 ounces to the gallon of soft water, and of from 4 to 16 ounces as a winter dressing for Vines and Fruit Trees. Has outlived many preparations intended to supersede it. Sold Retail by Seedsmen, in Boxes, 1s. 3s., and 10s. 6d. Wholesale by PRICE'S PATENT CANDLE COMPANY (Limited).

THE IMPROVEMENT OF LANDED ESTATES, By DRAINAGE, ENCLOSING, CLEARING, and the ERECTION OF FARM BUILDINGS and COTTAGES.

The Land, Loan and Enfranchisement Co. (Incorporated by Special Act of Parliament)

ADVANCES MONEY:

1st.—To the OWNERS of SETTLED and OTHER ESTATES, for the Erection of Farm Buildings and Cottages, and for the Drainage, Irrigation, Enclosing, Clearing and General Improvement of Landed Property in any part of the United Kingdom.

2d.—To the OWNERS of SETTLED ESTATES in ENGLAND, for the Erection or Completion of Mansions, Stables, and Outbuildings.

3d.—To LANDOWNERS generally, to enable them to subscribe for Shares in Companies for the Construction of Railways and Navigable Canals, which will beneficially affect their Estates.

4th.—To INCUMBENTS, for the Improvement of their Glebe Lands, by Drainage, and the Erection of Farm Buildings and Cottages.

5th.—To COPYHOLDERS, for the Enfranchisement of Copyhold Lands.

The amount borrowed, with the expenses, would be charged on the Estate benefited, and repaid by a rent-charge, terminating in twenty-five years.

No Investigation of the Landowner's Title is necessary. Forms of application, and all further particulars may be obtained of

Messrs. RAWLENCE and SQUAREY, 22, Great George Street, Westminster, S.W., and Salisbury; of Messrs. ASHURST, MORRIS, CRISP, and CO., 6, Old Jewry, London, E.C.; of Messrs. GILLESPIE and PATEKSON, W.S., 81A, George Street, Edinburgh, Agents for the Company in Scotland; and at the Offices of the Company, as below.

T. PAIN, Managing Director. EDWIN GARROD, Secretary.

ESTABLISHMENT FOR NEW AND RARE PLANTS. KING'S ROAD, CHELSEA, LONDON, S.W.

M. LOUIS VAN HOUTTE,

ROYAL NURSERY, GHENT, BELGIUM,

BEGS TO ANNOUNCE THAT HIS

BULB CATALOGUE, NO. 173 T.T., FOR THIS SEASON,

Is now ready, and will be dispatched to his numerous Customers.

Those not receiving the same may apply either to him or his Agents, Messrs. R. SILBERRAD AND SON, 5, Harp Lane, Great Tower Street, London, E.C., when a copy will be sent immediately, post-paid.

The CATALOGUE contains, as usual, an immense assortment of **HYACINTHS, TULIPS, CROCUSES, NARCISSUS**, and other **FLOWER-ROOTS**, as also a Selection of Miscellaneous **HARDY, TUBEROUS, and BULBOUS-ROOTED PLANTS**, and a Supplement of **STOVE and GREENHOUSE PLANTS, &c.** Our this season's Bulbs are, especially the **Hyacinths** (contrary to the general expectation), exceptionally fine, healthy, and sound, and cannot be surpassed, if equalled.

The CATALOGUE, No. 174 U.U., is in the Printer's hands, and will appear next month. It will contain a great variety of **INDIAN AZALEAS** and **CAMELLIAS**, to which several new ones, of great merit, have been added. Also **HARDY GHENT** and **MOLLIS AZALEAS, HARDY and GREENHOUSE RHODODENDRONS**, and a Descriptive LIST of large **SPECIMEN CAMELLIAS, &c.**

CABBAGE SEED FOR PRESENT SOWING.

CATTELL'S RELIANCE CABBAGE

Is the best sort to grow for spring cutting. Numerous Testimonials and my own trials prove it to be the earliest and best in cultivation. J. C. tried it this season with several sorts highly recommended by other Growers, and cut good Cabbage from his Reliance a month before the others were ready.

Free by Post, 1s. per Packet.

AN EXTRAORDINARY BOILER.—

During the Great Boiler Contest at Birmingham, in 1875, all Boilers were severely tested to prove their respective merits. One test was, "How long can each Boiler go without Night Attention?" However, one Boiler proved this to a surprising degree, as after being shut up for twelve hours (from 9 P.M. to 9 A.M.), it still retained its heat in 1000 feet of 4-inch pipes, and yet had more than 1 bushel of fire drawn from its furnace in the morning—equal, in point of fact, to seventeen hours of continuous firing. What a boon to Gardeners. This was **THE CHAMPION, Deards' Patent Close-Coil Boiler**, for Drawings and Prices of which send two stamps to

Messrs. DEARDS, Boiler Works, Harlow, who now have their Boilers at work in every county of England except three. Amateurs will also find **THE WONDER**, a smaller kind of Boiler, equally as satisfactory, and certainly "the best thing" out. Awarded five First Prize Silver Medals.

SPECIAL NOTICE.

LEWIS BROOK (late of the firm of Brook & Gallop) begs to inform the Trade that he has disposed of his share in the business of Seedsman and Florist to his late partner Mr. F. Gallop, but that he will still continue to carry on his business as a Fruiterer, Greengrocer, and Potato Merchant, at the old premises, 195, Western Road.

F. GALLOP begs to announce that having purchased Mr. Brook's interest in the Seed and Florist business, and finding larger premises necessary to meet the increasing demands of business, he has secured a large plot of ground at 30, Western Road, nearly opposite, and is erecting new premises, which will be entirely devoted to the purposes of the trade of Seedsman and Florist, and, as soon as completed, the business as now carried on by him will be transferred there.

Until the completion of the new premises, please address all communications to the old address, as above.

195, Western Road, Brighton.

F. GALLOP

(Late GEO. PARSONS),

SEEDSMAN AND FLORIST.

ESTABLISHED 1826.

MIGNONETTE, MILES' NEW HYBRID SPIRAL.

F. G. has much pleasure in announcing that he has purchased the entire Stock of the above-named New Mignonette, which is now acknowledged to be the finest variety ever exhibited. It caused quite a sensation at the great Show at South Kensington on May 2, 1877; being the variety that attracted the attention of Her Majesty the Queen.

DESCRIPTION.

This new Hybrid Spiral Mignonette, raised by Mr. Miles, and which has been so much admired by the Trade and Public generally, is far superior to any other in cultivation, the habit being dwarf and branching, with spikes often attaining a length of from 8 to 14 inches. By pinching the side shoots the centre spike attains a length of from 18 to 21 inches. The odour of this variety is superior to any other in cultivation. It is much hardier, and well adapted for market purposes.

Letter from Mr. MILES.

WM. MILES begs to announce to his numerous applicants that he has disposed of the whole of his Stock of New Hybrid Spiral Mignonette to Mr. F. GALLOP (late Geo. Parsons), as exhibited by him at the Royal Horticultural Society, obtaining a Certificate, May 15, 1876, and again, June 21, 1876, also at the Royal Botanic Society, Regent's Park, same date. (Signed) WM. MILES.

Extract from the "Journal of Horticulture and Cottage Garden," June 7, 1877.

This is the finest Mignonette that has come under our notice. It is the same variety that attracted the attention of Her Majesty the Queen at the great Exhibition at South Kensington, on May 2, 1877.

Extract from "The Garden,"
April 21, 1877.

NEW LARGE FLOWERING MIGNONETTE.—At the Horticultural Exhibition at South Kensington, on Wednesday last, Messrs. BROOK & GALLOP, of Western Road, Brighton, exhibited some remarkable examples of Miles' Hybrid Spiral Mignonette, a robust and floriferous variety, and certainly the largest flowered form that I have yet seen, producing as it does erect columnar spikes, 6 inches or more of which are covered with fully expanded blossoms. As a vigorous free growing variety, for ordinary decorative purposes or for Market, this Mignonette should soon become popular, seeing that it is as fragrant as the older forms, and that it possesses a very distinctive appearance.

DIRECTIONS for SOWING.

Sow in the open ground in April, and for succession throughout the summer, covering the seeds about quarter of an inch deep. For Winter and Spring Flowering, sow in pots of loam, mixed with a little leaf mould, in August and September, and protect from frost in cold frame. For early flowering, sow in February and March, on a slight bottom-heat. Thin out or transplant before the plants get crowded.

ELECTROS OF THIS BLOCK, 5/- EACH.

NONE GENUINE UNLESS THE PACKET BEARS MY NAME AND ADDRESS.
2s. 6d. per Packet. Price to the Trade on application.

As the Stock of Seed is very limited, early Orders are requested to ensure a supply.

THE BRIGHTON SEED WAREHOUSE, WESTERN ROAD, & 30, CORN EXCHANGE, BRIGHTON.

All Communications to be Addressed to Western Road.

Wholesale Agents—Messrs. HURST & SONS, Seed Merchants, 6, Leadenhall Street, London, E.C.

SATURDAY, JULY 28, 1877.

THE FOLKLORE OF THE ROSE.

(Continued from p. 38.)

THE popularity which the Rose attained in this country at an early period led to its employment in different ways. Thus we find it occasionally taken as a substitute for rent. In 1576 the then Bishop of Ely granted to Sir Christopher Hatton a great part of Ely House, Holborn, for twenty-one years, on condition that the tenant should pay annually, on Midsummer Day, a red Rose for the gate-house and garden, the Bishop reserving to himself the right of walking in the gardens, and gathering every year 20 bushels of Roses. The good Bishop would be somewhat startled could he see the changes which have passed over his "garden" since that period. Mr. Ingram, in his *Flora Symbolica*, says that Sir William Clapton granted to Thomas Smith a piece of ground called Dokmedwe, in Hanstede [? Hampstead], for the annual payment of a Rose, at the nativity of John the Baptist, to Sir William and his heirs, in lieu of all services; "dated at Hanstede, on Sunday next, before the Feast of All Saints, 3 Henry IV., 1402."

The Rose has in all times and in all countries been a favourite flower for planting and strewing upon graves. Both the Greeks and Romans employed it in this manner, and sometimes even annexed codicils to their wills commanding that their graves should yearly be strewn or planted with Roses. Antony, when dying, begged of Cleopatra that she would scatter perfumes upon his tomb, and cover it with Roses. In Turkey, according to Phillips, a Rose is sculptured on the monuments of such women as die unmarried; while in Poland they cover the coffins of children with these flowers, and throw them from the windows as the funeral procession passes along the street. Roses are also among the flowers planted upon graves by the Chinese. In the German portions of Switzerland both old and new churchyards are called "Rose gardens," and the same name is given to many ancient heathen burial places in the depths of the forests. The graves of Catholics and Protestants are sometimes distinguished by red and white Roses respectively; but this is a modern observance.

Among ourselves, the planting of Roses upon graves was formerly general in South Wales, and was also observed in many parts of England. Thus Camden says that at Ockley, in Surrey, the custom of planting Rose trees on graves, especially on those of young men and maidens who had lost their lives, had been observed "time out of mind," but it is not now retained in that locality. A similar occurrence took place at Barnes, in the same county, where one Edward Rose, a citizen of London, who died in 1653, bequeathed £20 for the purchase of an acre of land for the poor of the village, on condition that a number of Rose trees were planted round his grave, and duly tended. A similar request was made by one Thomas Stevens, a poor and aged man who is buried at Stoken Church, in Oxfordshire, who desired his son to dress his grave with flowers on the annual recurrence of St. Peter's Day. The wild Rose trees growing in Lowton Field, in Yorkshire, are said to have been originally planted upon the grave mounds of those who fell in the combat between the Lancastrians and Yorkists in

1461 by the survivors of the fray; and it is locally believed that Rose trees transplanted from the "bloody meadow," as it is called in the neighbourhood, will not grow elsewhere.

Besides such matters as the foregoing, there is a good deal of folklore pure and simple connected with Roses. Wilsford in his *Nature's Secrets* says that "when Roses or Violets flourish in autumn, it is an evil sign of an insidious plague the year following, or some pestiferous disease." A writer in the *Connoisseur* (No. 56), after describing the well-known Midsummer Eve love-charm connected with the Orpine, goes on to say:—"Our maid Betty tells me that if I go backwards, without speaking a word, into the garden, upon Midsummer Eve, and gather a Rose, and keep it in a clean sheet of paper without looking at it till Christmas Day, it will be as fresh as June; and if I then stick it in my bosom, he that is to be my husband will come and take it out." It is probably to this charm that Herrick refers in the *Hesperides*, when he says, speaking of a bride—

"She must no more a-maying,
Or by rosebuds divine
Who'll be her Valentine."

In Thuringia the Rose holds a similar position as a love-charm; a maid who has several lovers will name a Rose-leaf after each, and then scatter them upon the water; that which sinks the last representing her future husband. In some parts of Germany it is customary to throw Rose leaves on a coal-fire as a means of ensuring good luck. In Germany, as well as in France and Italy, it is believed that if a drop of one's blood be buried under a Rose-tree, it will ensure rosy cheeks. The Rose is also associated in Westphalia with a charm against nose-bleeding and other hæmorrhages. This charm consists in the repetition of the words—"In Christ's garden stand three Roses, one for the good God, the other for God's blood, the third for the Angel Gabriel: blood, I pray you, cease to flow." In Suabia it is somewhat different:—"On our Lord's grave spring three Roses, the first is Hope, the second is Patience, the third is the will of God: blood, I pray you, be still."

In former days the red and the white Rose were supposed to possess different and often antagonistic properties. Thus a MS. of the time of Henry VIII. prescribes among the things that are "good for the brayne," "to smell the rede Rose and to wasshe the temples wth the water of rede Roses styll'd;" while "to smell to a whytte Rose" is reckoned among things "evell for the brayne." In the seventh edition of Withering's *Arrangement of British Plants* (1830) the same idea is maintained. Speaking of white Roses, it is stated that "besides the cordial and aromatic virtues which reside in their volatile parts, [they] have an aperient effect, which remains in the decoction after distillation. The red Rose, on the contrary, has an astringent and gratefully corroborant virtue." It is hardly necessary to say that this idea has no foundation in fact, or that the medicinal properties of the Rose are quite unimportant. This, however, was not always considered to be the case, for Langham, in his *Garden of Health* (1633), gives no fewer than a hundred and forty-one ways in which it may be employed. In a curious little work, entitled a *Book of Fruits and Flowers*, published in 1656, are some quaint recipes for the employment of Roses, of which the following may serve as samples:—

"SYRUP OF ROSES.

"Take Damask Roses, clip off the white of them, and take 6 oz. of them to every pint of faire water, first well boyled and simmered; let them stand twelve hours, as you doe in the syrupe of Violets, wringing out the Roses and putting in new eight times, then wringing out the last put in onely the juice of 4 oz. of Roses, so make it up: if you will put in Rubarb, take to every two drams, slice it, string it on a thred, hang it within the pot after

the first shifting, and let it infuse within your Roses. Some use to boyle the Rubarb in the syrupe, but it is dangerous. The syrupe purgeth chollier and melancholy."

"TO PRESERVE ROSES.

"Take 1 lb. of Roses, 3 lb. of sugar, 1 pint of rose-water, or more. Make your syrupe first, and let it stand till it be cold, then take your Rose leaves, having first clipp'd off all the white; put them into the cold syrupe, then cover them, and set it on a soft fire, that they may but simmer for two or three hours; then while they are hot, put them into pots or glasses for your use."

Langham gives a recipe for making "Vinegar of Roses," which runs thus:—

"Gather them before they be full blowne in dry weather, lay them on a board halfe a day, then put them into vinegar, close stop't twenty-four houres; then stampe them and set them in glasses in the sunne all summer, then streine it and use it: if it be renewed with Roses every tenth day it is the better; it may be made with wine, either white, red, or claret." For "Sugar Rosat," "stampe one pound of new gathered Roses with foure pounds of sugar, and sun it in a glasse thirty daies. It may be kept three yeares."

Although they can scarcely be considered as possessing important properties, Roses are still employed in medicine. An infusion of red Rose petals is employed as an agreeable vehicle for other medicines, and a confection of them is also in use. The Rose employed for this purpose is *Rosa gallica*, an Eastern species which has been widely cultivated from a very early period, and exists in gardens under a variety of forms. The authors of *Pharmacographia* tell us that the Provins (often erroneously written Provence) Rose is a variety of this species, so called from having been long cultivated at Provins, a small town about 60 miles south-east of Paris, where it is said to have been introduced from the East by Thibaud VI., Count of Champagne, who died on his return from the Crusades in 1254. Be this as it may, Provins became much celebrated both for dried Rose petals and for the conserve, syrup, and honey of Roses made from them. The red Rose is cultivated at Mitcham to a small extent, under the erroneous name of Damask Rose; it is also grown for the druggists in Oxfordshire and Derbyshire, and more extensively in some parts of France, Holland, and Germany. The Cabbage Rose (*R. centifolia*), which is the species chiefly employed in the making of Rose-water, is also cultivated to a small extent at Mitcham, and in the market-gardens to the west of London. The attar or otto of Roses is yielded by a variety of *Rosa damascena*, a plant which, although usually regarded as distinct, is looked upon by Mr. J. G. Baker as most probably a cultivated race of *R. gallica*. Messrs. Fluckiger and Hanbury say that the earliest allusion to the distillation of Roses that they have met with is in the writings of Joannes Actuarius, who was physician to the Greek Emperors at Constantinople towards the close of the thirteenth century. *B. M.*

New Garden Plants.

ODONTOGLOSSUM MADRENSE, *Rehb. f.*

I have often been asked, what is this species? It is that very same species that Mr. Ortgies once gave into the hands of Messrs. Veitch under the name of *O. maxillare*. It was well represented as such in the *Botanical Magazine*. To a certain extent I was indeed responsible for this name having been given. Mr. Roetz sent three remains of faded flowers, the only vestiges he gathered when the plant was collected, and those Mr. Ortgies of Zurich kindly sent me for being named. (Ah to name such *beaux restes*—worthy rivals of those crushed, smashed scraps which Messrs. the Editors of the *Gardeners' Chronicle* enjoy so much!) They are at hand. Well, I thought of *O. maxillare*, Lindl., and maxillare it was named. But, as it is with all mistakes—"post equitem sedet atra cura"; finally the plant flowered, and I saw immediately that it was different, totally different—new, quite new. I named it *O. madrense*, and described it. It is indeed in the way of the old *Odonoglossum nebulosum*, but far more slender, and for this reason, according to my taste, far more elegant. The flowers

are white, beautifully adorned with broad greenish, or reddish brown spots at the base of the petals and sepals, now and then with a blotch scattered somewhere. The white column is densely covered with hairs at its base. It appears to be a very rare plant, only seen by the lynx-eyed Mr. Roetz, and, as it appears, now by Mr. Franz Klaboch, Mr. Roetz's Czechian nephew, who has complained bitterly how difficult it is to find the plant. Ah, yes, many plants are difficult of access, and one requires the fullest enthusiasm of plant love to meet with them. *H. G. Rehb. f.*

ERIA DAYANA, *n. sp.*⁸

A curious species of the "flavæ" section bearing the closest affinity to *Eria sicaria*, Lindl. The type of this species has depressed narrow leaves, and the trilobed lip, with a narrow anterior lobe and a single long callus. Our species is totally different. It has a lip as broad at the apex as at the base, with very narrow side lobes, a short claw, and an emarginate anterior lobe. The callus is longitudinal over nearly the whole of the length of the lip, and at the apex it goes back each side in a lateral short shank. The flowers are arranged in a loose raceme, whose rachis is white woolly as are the flowers on the outside, while the bracts, which nearly equal the inferior stalked ovaries, are naked. The colour of the flowers is honey-yellow. The lip has numerous brown blotches, and the callus is nearly black. The plant has a creeping rhizome, small ovoid pseudobulbs, with usually three very leathery linear-lanceolate acuminate leaves, which are a span high. The flowers are smaller than those of *Eria flava*. I obtained it from my second oldest English correspondent, our excellent Orchidist, Mr. J. Day. *H. G. Rehb. f.*

VANDA CÆRULESCENS, *Griff.*, LOWIANA.

This is an exceedingly pretty novelty. Give a *Vanda cœrulescens* Boxallii an amethyst coloured middle segment of the lip, and a little amethyst dot at each end of sepals, and you have this nicety, dedicated to Mr. Lowe, who was so lucky to introduce it. *H. G. Rehb. f.*

A WORKING-MEN'S FLOWER SHOW.

THE impetus which has been given to plant growing by parochial flower shows both in country villages and in great towns—where, as we have lately seen in Westminster, the poor are encouraged to beautify the dusky rooms of their courts and alleys by the introduction of plant life—is already producing good results. The movement is greatly helped forward by such inexpensive liberality as that manifested annually in the Government parks and gardens by the distribution of bedding plants before the commencement of the frosts; by such graceful acts as the distribution of Hyacinth bulbs which takes place in Manchester, we believe, every winter; or by such meetings as that held last month at the Liverpool League Hall, when a handsome collection of plants, contributed for the purpose by various donors, was distributed by Father Nugent to the poor working-women whom he has induced to abandon the use of intoxicating drink. But it must not be forgotten that, besides these efforts, which are either originated or mainly supported by the so-called higher classes, there are in some districts, and notably in Lancashire, botanical societies supported entirely and organised throughout by working-men; and these societies, however humble their organisation, have existed for a very considerable period, and have done and are still doing very useful work. Exactly a century ago there was one of these working-men's botanical societies at Eccles, six miles from Manchester, which numbered about forty members, and similar associations were soon established at Oldham, Aston-under-Lyoe, and other Lancashire towns. This was long before the more aristocratic, but scarcely more useful, Horticultural Society of London had started upon its career. These district societies were in the habit of meeting together occasionally for comparison and mutual improvement; and these meetings, which were usually held on Sundays at some respectable public-house, were conducted with great propriety until towards the close of the last century, when they were temporarily discontinued. They were resumed, however, after a few years, and have since then been carried on with more or less regularity, the botanical societies of Lancashire,

⁸ *Eria Dayana*, *n. sp.*—Aff. *Eria sicaria*, Lindl.; pseudobulbis ovoidibus triplyllis; foliis linear-lanceolatis locatis valde coriaceis; racemo laxifloro tomentoso; bracteis scarificatis linear-lanceolatis nudis ovaria pedicellata inferiora subquantibus; ovaris pedicellatis tomentosis; sepalis triangularibus tomentosis, tepalis angustioribus calvis; labello trilobo latis lateralibus oblongis angustis; lobo antico ab isthmo brevi dilatato oblongo emarginato; callo ligulato per lineam longitudinalem, ante apicem utriusque crure retrorso.—Ind. Or.; coll. Day.

Cheshire, and Derbyshire being united in annual gatherings, while more local associations have also their annual and other meetings. Curiously enough Eccles, the *fons et origo* of these associations, does not now itself possess a botanical society. The earliest society, after the interregnum to which we have alluded, was the Middleton District Society; that at Prestwich, the nearest to Manchester, was established on September 11, 1820. The meetings of these societies are almost always held on Sunday afternoons, a circumstance which may scandalise those who would underrate the liberty conveyed in the precept that "the Sabbath was made for man, and not man for the Sabbath," and although they take place at public-houses they are conducted in so orderly a manner as to leave no ground for censure. A meeting at Prestwich was, indeed, once interfered with by the authorities, but the botanists were not really to blame. Several of the societies possess good libraries and large herbaria; that at Prestwich fills about 200 volumes. The Stockport Botanical Society, as well as one or two others, possesses also a good collection of living plants, many of which have been obtained from distant localities by members who have made special excursions for the purpose.

The Bury Working Men's Botanical Association has just (Saturday, July 7) held its annual exhibition and gala, and a brief account of the proceedings thereat may prove interesting to some at least of our readers, more especially as on the following day one of the amalgamated meetings of the Lancashire Botanical Association took place. Owing to the unfavourable state of the weather the attendance, as well as the number of entries for the different prizes, was but limited; moreover, the plant-show was, as we are informed, very inferior in quality to those of other years. The following is a list of the classes in which prizes were awarded:—Six wild flowers, three prizes; wild bouquet, two prizes; two wild plants in bloom, two prizes; twenty-four wild flowers, two prizes; four garden blooms, three prizes; six Roses, two prizes; cultivated bouquet, one prize; two greenhouse plants in bloom, two prizes; three stove or greenhouse cut blooms, three prizes; British Ferns, three prizes; with an extra prize for the most curious plant shown, which was obtained by the exhibitor of a Pitcher-plant. Most of the sets of wild flowers would have been disqualified by a severe critic. It appeared that any plant included in British lists was allowed a place among the wild ones; but besides these *Spiræa aruocosa*, a foreign *Lavatera*, and other undoubted foreigners were noticed. The greenhouse plants were very poor, and very sparingly represented, the 1st prize being taken by a scarlet *Pelargonium* and a *Heliotrope*. A curious object was put in as a claimant for the last prize—it was a manufactured specimen, mainly constructed of Dog's-tail-grass (*Cynosurus cristatus*), and was probably sent as a joke. It should be mentioned that the tent in which the show was held was flanked at the entrance by two fine specimens of *Heracleum sibiricum*, about 10 feet high.

On the next afternoon (Sunday) the eighth annual meeting of the Lancashire Working Men's Botanical Association was held in the same tent, at which there was a large attendance of representatives from the various societies belonging to the Association. The following districts were represented by delegates:—Rochdale, Middleton, Prestwich, Swinton, Bolton, Heywood, Milnrow, Farnworth, and Bury. The chair was taken by Mr. R. H. Alcock, of Bury, who is the President of the Local Natural History Society, and has done much to help forward the study of natural science in the district. He delivered a brief address upon the work of the Lancashire botanists, and, somewhat to our regret, defended the practice of some of them in introducing plants to localities where they were likely to establish themselves permanently. The most interesting portion of the meeting then commenced. "As specific discrimination and accuracy in botanical nomenclature are the chief objects sought to be obtained by the aid of the meetings"—to quote from the information given to the members—"all persons who attend are hereby respectfully solicited to bring with them such specimens of plants, either indigenous or exotic, but particularly the former, as they can conveniently procure." In compliance with this request, most of the delegates present, as well as other members, brought specimens; and these were laid out on a long bench, in accordance with the Linnean system, that method being the one always employed on these occasions. In consequence of the weather, fewer specimens than usual were

exhibited. We are indebted to Mr. Alcock for a complete list of the Phanerogams and Ferns shown, from which we select the following as among the most interesting:—*Hippuris vulgaris*, *Utricularia minor*, *Valeriana pyrenaica*, *Plantago maritima*, *Sambucus Ebnulus*, *Geranium pæneum*, *Pyrola rotundifolia*, *Ligusticum scoticum*, *Atropa belladonna*, *Hottonia palustris*, *Glaux maritima*, *Carex hordeiformis*. Mr. Percival, the President of the Association, who occupied the post of botanical referee, named each plant as it was handed to him, giving not only both an English and the Latin name, but occasionally information as to the local habitats or medicinal properties of the plants under notice. By one of the rules of the association, the specimens exhibited "become the property of the President, who shall dispose of them in such a manner as he may think will give general satisfaction." In this way a distribution takes place, and both useful information and specimens are given and received. A collection of mosses was also named; and Mr. Percival discharged his duties in a manner which fully accounted for the respect and esteem in which he is held by his fellow-botanists.

While wishing long-continuance and all possible success to these associations, we are glad to learn from Mr. Alcock that, so far as Bury is concerned, many of the good men among the botanists are joining the Natural History Society. Such a proceeding cannot fail to be beneficial both to the men and to the Society: the former will have the opportunity of mixing with minds somewhat more cultivated than their own, while the Society will gain much from the addition of new and active members to its ranks. The Lancashire working-men have an independence and an abruptness of manner which is at first somewhat startling to a Southerner; but they have with this an amount of perseverance and firmness which cannot fail to command the esteem of those who can look beyond the rough exterior to the practical energy and genuine industry which that exterior at first sight conceals. B.

[We should be among the last to say aught against innocent recreation, and specially against the study of God's works on the Sabbath, but now that the Saturday half-holiday is a recognised institution, it would be surely better to hold the meetings in question on that day, in any case to avoid meetings at a public house, and, last, to give up the Linnean system as quite obsolete! EDS.]

GARDEN VEGETATION FOR JUNE.*

THE weather during June has, upon the whole, been pleasant, but by no means warm. The lowest temperatures experienced were during the nights of the 7th, 12th, 13th, 16th, 17th, and 24th, indicating 43°, 39°, 41°, 37°, 41°, and 40°, while the highest night temperatures were on the 4th, 10th, 21st, 26th, 27th, and 29th, indicating 52°, 53°, 52°, 58°, 55°, and 55°. At this time (June 30) vegetation is still much behind. Last season was considered a late one, but this year many trees are still later, both as regards leaf and flower: A few instances may be quoted to show the difference, the same plant or tree being fixed on each year for the purpose. The following Ash (*Fraxinus Ornus*) was in perfection this year on June 28, in 1876 on the 15th, and in 1875 on the 7th. The common Elder (*Sambucus nigra*) did not show its first open flowers this year till June 27, in 1876 on the 16th, and in 1875 on the 5th. The Portugal Laurel had no flowers expanded on June 30, while in 1875 it was in full flower at that date. During the same year the *Cratægus tanacetifolia* was recorded as being in full bloom on June 25, while no flowers are yet to be seen open. The ordinary Thorns have been very full of bloom, particularly the single white and red, both being in perfection on the 25th. The Lime tree (*Tilia europæa*), although covered with blossom-buds, has as yet no expanded flowers.

The following trees were observed to be in a free-flowering condition on June 30, viz., Laburnums, double and some white Hawthorns, scarlet-flowering Horse Chestnuts, flowering Ash, and many varieties of Sorbus, while the common Horse Chestnut showed its first open flowers on June 20. They were exceedingly poor, and have been so throughout—scarcely a tree, except in sheltered situations, having perfect leaves.

* Read at the July meeting of the Botanical Society, Edinburgh, by Mr. M'Nab.

The large *Sorbus domestica* in this garden, which has been occasionally noticed for its peculiarity of flowering, has this year the western half covered with bloom, while last year it was the eastern half. This alternation of flowering has been observed on the same tree for several years. The tree has two main branches proceeding from a stem 7 feet high and 5 feet in circumference.

In my report for May I stated that a peculiar yellow tint had been observed on the young foliage of many trees, particularly when late in coming out. It is somewhat remarkable that the older trees of what is known as the Corstorphine Sycamore, celebrated for its early yellow foliage, which afterwards becomes green, have this year been late in coming into leaf, and were deficient both as regards colour and duration in their coloured condition.

The American Oaks, more particularly the species known as *Quercus rubra*, has this year been late in coming out. All the leaves have a peculiar yellow tint.

Subjoined is a list of trees whose foliage was still behind on June 30:—Sugar Maple, scarlet American Oak, Weeping Ash, small-leaved English Elm, Walnut, Turkey Oak, Hornbeam, *Celtis occidentalis*, *Ostrya virginica*, Juglans alba, Tulip tree, *Ptelea trifoliata*, Robinias, Catalpa tree, Platanus, and *Taxodium*.

Besides trees, perennial, herbaceous, and annual plants are very backward.* On the rock garden 336 species and varieties were counted in flower on June 30, while last year at the same date the number was 452 species and varieties.

List of some of the more conspicuous plants in flower in the Rock Garden.

<i>Arenaria balearica</i>	<i>Meuzesia polifolia variegata</i>
" <i>grandiflora</i>	<i>Onosma echinoides</i>

THE GRAPE VINE AS A DINNER-TABLE PLANT.

I WAS very much struck the other day, on a visit to Drumpellier, the seat of Colonel Buchanan, to see quite a bevy of Vines in pots about 5 inches diameter, and each Vine not more than 20 inches in height, with one and two bunches of Grapes each, from ½ lb. to ¾ lb. weight, in first-rate condition as to berry, and in fair colour. On further examination I found that Mr. Lewin, the clever contriver of this natty plan, had pot Vines tied down to a single wire about 6 inches from the stage, trained like a cordon Apple tree. On each of these Vines were springing up perpendicularly the laterals with bunches, and in order that they might be made serviceable for detachment, when ripe, they were inveigled into a 5-inch pot to root away on their own account precisely like the larger ones. The pots were full of roots, and stood regularly distributed along the top of the high kerbstone common in Pine stoves, not less than six, and in some cases eight, to each Vine rod. To make the whole more dinner-table like, sprays of *Selaginella* of the common kind were made to clothe the surface of the pot, and the laterals were kept well rid of shootlets by pinching.

* On July 12 it was impossible to procure in the fields on this side of Edinburgh specimens of Wheat, Oats, and Barley in a state for examination at the Botanical Garden, a circumstance of very rare occurrence at this particular date.

This is a much better plan than taking the rod through the bottom of the pot; moreover, it enables the grower to have six or more plants to each Vine, which is a great deal for a pot Vine treated in this way. On the dinner-table the plants, laden with fruit *bona fide*, are of the most captivating character, and look as fresh a week after as they do the day they are placed upon the tables. The plan is so excellent and so novel that I thought a simple record of it might be interesting to your readers in general, and to pomological readers in particular.

I might add that Mr. Lewin finds it attended with better success not to be too quick in inserting, or rather placing, the layers on the ground within the limited pot area (for there is really no insertion), because of the tendency to weaken the food supply from the principal store pot if the laterals were provided with their independent roots at too early a stage.

The sorts grown are chiefly Black Hamburgh, with Buckland Sweetwater as a white; and there is a succession of them, some doing duty a fortnight ago, others as late as can be. The plan is of quite recent adoption with Mr. Lewin, and his employer, who is pretty exacting in matters of taste in connection with indoor decoration of all kinds, is quite delighted with his Tom Thumb fruiting Vines. *Fames Anderson, Meadowbank Nurseries, Uddington, July 24.*

CIRCULATION OF THE SAP.

THERE are one or two points in your leader of last week on my paper on the flow of sap as to which I should like to remove what I think is a misapprehension on your part. I do not at all reclaim against the tone of your article. I hope that, had I been in your position, I should have had the sense to treat it in the same way. It would never do were the leaders of public opinion on scientific points to allow themselves to be blown about by every breath of doctrine, or too readily to welcome every innovation, I therefore perfectly subscribe to the propriety and wisdom of the caution you exercise; but then, although you may think that I am perhaps running too fast, that is no reason why you should handicap me with more than the weight that properly belongs to me, but this is what I think you do when you say that my views "would if accepted negative all that has been laboriously acquired by chemists and vegetable physiologists from Priestley downwards." Now nine-tenths of what has been so done does not apply to my inquiry at all. The researches to which you allude mainly relate to growth. My inquiry does not touch growth. I distinctly point out in my paper the different position which growth occupies from assimilation. Growth goes on by day or by night intermittently so long as there is matter to build with; assimilation only takes place while the plant is being supplied with food—when that is stopped assimilation stops too. My inquiry relates only to the direction in which the food is supplied for assimilation, and that surely cannot affect growth. It cannot matter to the cell whether the assimilated matter on which it is to work is presented to it from above or below. Therefore, so far as regards growth, I submit that it does not enter into the inquiry at all. And as regards assimilation the question is limited to two points—first, whether the process of assimilation is confined to the leaves (a proposition which I dispute); and second, whether matter elaborated in the leaves finds its way down from them to other parts of the plant or not. I do not interfere at all with the process or existence of elaboration or assimilation in the leaves. I believe it goes on there as in every other growing part of the plant—the breaking up of the carbonic acid gas therein (not indeed under the influence of light, for I dispute the power of light to effect the chemical changes—its possession of such power as far as I can learn is a pure assumption), the retention of the carbon, and the elimination of the oxygen to which you refer may all be conducted very much as you describe. All that I say is, that the plant gets the carbon so treated from the roots and not from the atmosphere. What does it matter to the process where the carbon comes from, provided it is there? One word more by way of explanation of what I imagine to be the purpose of the leaves: I quite agree with you that they are not store-houses, I also agree that they are factories, or rather machinery. But then they are no more factories than any other growing part of the plant is, and in addition

to their general functions each is also a factory for its own uses. The leaf elaborates the materials necessary for its own structure and to enable it to fulfil the special functions with which it is charged, which, as I think, are mainly that of a very powerful pumping apparatus. When there is more material produced than is required for the leaf, instead of being distributed and sent back to the rest of the plant it is, according to my view, carried past the petiole, and employed in making more leaves. This is the crucial point on which we differ. You think that the "manufactured products of the leaf are drafted upwards, downwards, sideways, according as circumstances necessitate or requirements dictate." I believe that wherever they are once elaborated there they remain—that each structure and each element, when once dealt with (elaborated), has a particular function for which it is fitted, and a particular post which it does not quit, and that it cannot be sent like a "handy man" to do odd jobs in different parts of the plant or to give additional force where more strength is needed. *Andrew Murray.*

— The value of new opinions depends materially upon the nature of the facts by which they are supported. The introduction of a foreign body into the stem of a tree, whilst productive of interesting results, can hardly be accepted as pointing to a clear and definite fact. Mr. Murray lays great stress upon the fact that out of the myriads of scions grafted and budded upon stocks we see no influence exercised by the scion upon the stock, such as might be looked for if there were a downward

FIG. 19.—PHYLLOXERA VASTATRIX.

flow of sap; but I insist that that fact proves nothing, for the simple reason that out of the myriads of stocks used for budding and grafting the stock is found to exercise comparatively little influence upon the scion. Mr. Murray holds that the stock does exercise an influence upon the scion; perhaps so, but not in the direction of altering its character, only in influencing its growth. Out of the myriads of Briers used as stocks for the Rose, who ever heard that the budded scion partook in consequence of any of the features of the Brier? A Quince stock does not impart to the Pear a Quince character or flavour, neither does the wild Crab stock affect the quality of the Apple. If it cannot be shown that in the unquestioned ascent of the sap the stock effects any change upon the character of the scion the argument that the absence of any evidence of change being wrought in the stock by the influence of the scion is proof against the theory of the downward flow is utterly inconclusive, indeed it points to the probable fact that the stock is simply a medium for the conveyance of nutrition in the form of sap from the soil to the leaves, and nothing more. Now I am tempted to offer for consideration a few illustrations that occur to me. The branch of a Cherry tree here was rung last winter by taking out all round it the bark to a width of about one-eighth of an inch, the purpose being to see if fruitfulness could thereby be induced. The result is that now the wood immediately above the cut is nearly twice as stout as is the wood below it. Now, as I understand Mr. Murray's theories, I should assume that, looking at the severe check given by the cut to the upward flow, the wood below ought to be the stoutest, instead of the wood above. I think the result, however, rather points to the conclusion that the sap did ascend in spite of the cut, was duly assim-

lated in the leaves, and then returned to build up the plant, but could not pass below the cut because its channels of passage downward through the "cellular layers of the inner bark" were removed. Still, it may admit of another explanation. That familiar plant, the Potato, presents features worthy of consideration in discussing this subject. Is the tuber generated by direct root-action, or is it the result of sap that has been assimilated in the leaves, and has returned to build up the substance of the tuber? Does the tuber contain constituents other than those abstracted from the soil through the agency of the roots? If it be shown that portions of these constituents consist of substances that must have been the product of the leaves, the fact will be conclusive in favour of the return of the sap theory. The size and consistence of the tuber of the Potato depends chiefly upon the growth of haulm and development of leafage, and where the latter is abundant the tubers are proportionately large. The connection between the size of tuber and the strength of the haulm is so absolute that Potato growers have held invariably that the latter tended to elaborate the former. I believe this notion is held by cultivators of all root crops on the assumption that the more leaf surface the more completely was the ascending sap assimilated to the building up of the root bulb or tuber on its return. The Potato specially differs from most other roots in the fact that the tubers do not lie in the plant in the position of intermediaries between the rootlets and the leaves. That such is the case with all bulbous-rooted plants we know, but an examination of the root of the Potato shows the roots are independent of the tubers, the latter being found at the extremity of separate branches. The first rooting of a cutting appears to present an illustration against Mr. Murray's theory. Out of what are the rootlets formed if not out of stored-up sap, and if to form these roots there must be a downward attraction in the cutting, why may it not also exist in the plant? A cutting has from the first to depend upon what moisture it is capable of extracting from the soil, but this without roots cannot prolong life indefinitely. Are the roots the product of the moisture as extracted from the soil, or exuded from the base of the wound by the force of a downward pressure on the sap exercised by the atmospheric conditions of light, air, and warmth upon the leaves? At all events, it would seem conclusive that, in the case of cuttings, rootlets must first be formed from out of the sap in the branch before the branch can extract nutriment from the soil; and if this be so, then the downward flow of the sap is proved. *D.*

THE PHYLLOXERA.

GRAPE growers are as much interested in the Phylloxera as are the Potato growers with the Colorado beetle, on which account we think it well to give an illustration of the manner in which the Grape louse (fig. 19) affects the leaves of the Vine. Many specimens of "warts" are sent to us under the impression that the leaves so affected are attacked with Phylloxera. The illustration (fig. 20), taken from a specimen recently sent to us, will show better than words how the Phylloxera attacks the leaves, while the smaller cut is Professor Westwood's original illustration of the insect. We may say that we have received many more specimens of the roots infected with the insect than of leaves.

GLEANINGS FROM THE ROSE SHOWS.

(Concluded from p. 75.)

THE readers of my paper in the last number of the *Gardeners' Chronicle* (July 21) are requested to note two or three little errors, arising, probably, from illegible copy. "Vallambrosa" should have been "Vallambrosa" [Valombrosa is the more correct. Eds.]; the second, "Baron Bonstettin," "Baron Chaurand;" a comma should be between "the Gloire" and La France, and Marie Cointet—only an exhibitor's Rose. By the way, upon an inspection, since my last remarks were written, of several specimens at some large nurseries, the colour of this Rose, when in character, struck me as closely resembling that of the flower of the Oleander. This view was assented to by the friend to whom I communicated it, and, further, that the precise tint is unique amongst Roses. On the same occasion I also noted instances of the injurious propensity that Captain Christy has to grow out from the stock, after the manner of Maréchal Niel—not a common idiosyncrasy amongst H.F.'s.

In the course of note-taking, besides varieties already remarked upon, the writer singled out certain kinds for notice other than from the mere exhibition

point of view—that is, as to their character and uses under actual cultivation. At the shows blooms are presented in the state of full expansion, or nearly so, while many kinds really display their highest beauty when in the bud. At this stage they are particularly suited for the "button-hole," a mode of using flowers which has hitherto received little artistic consideration, and for bouquets when small, and Roses form their chief constituents. For such purposes Teas and the less exaggerated show monstrosities amongst the hybrid perpetuals are in admirable keeping. What can be more charming than the contrast afforded by a half-opened bud of *Maréchal Niel* or *Madame Falcot* against one of *Prince Camille de Rohan*, *Louis van Houtte*, or *Xavier Olibo*, or *Niphotos* and *Madame Knorr*, one of the loveliest *Roses* in bud we have? Illustrations might be multiplied *ad infinitum*, but the suggestion is sufficient for rosarians with an eye for colour harmonies and contrasts. The kinds with long buds should be selected as the best.

The *Roses* most remarkable for evenness of form were, first, *Félix Genero*, the finest model perhaps we have—would that in shape we had examples resem-

Let any one take half a dozen representatives of certain much-puffed novelties, and having picked them to pieces, count the petals, and compare them in number with the old *Cabbage Rose*. The lesson will be startling. Again, as to the colours of *Roses*. Purity seems to be a point almost ignored, especially in the tinted approximations towards white. In many cases, too, there is a distinction without a difference, so many are alike. If any rosarian wishes to realise this fact, let him, as the writer has often done, go on a tour of inspection through fifty or a hundred thousand *Rose* trees. If, before half his promenade is over, he is able to distinguish any individual *Rose* from another, his powers of vision must be of an entirely exceptional order.

At every successive show the question involuntarily arises in the mind—Can no more elegant mode be invented or contrived for displaying *Roses* on the stands? Are the green tray-like boxes at present in use the limit of the artistic resources of exhibitors, or is (too often) half-dry and dingy moss the only medium that can be discovered as a surfacing to set off the blooms? Finally, should *Roses*, which are not

Mueller says:—"Is there any state of the *Ficus australis* in *Illawarra* or elsewhere in *New South Wales* producing a *Banyan*-like growth such as occurs in the *Ficus columnaris* of *Howe's Island*?"

My attention was directed to a tree of *Ficus australis* growing in the *Sydney Botanic Gardens* close to the fence, which had sent down firm trunks, and several of the roots of various sizes were advancing. There are also some old trees at *Watson's Bay*, near the *South Head*, *Port Jackson*, which have also sent down large and firm roots, so, as far as regards this tree, it may be considered as an established fact. At *Howe's Island* there is a noble *Banyan* tree, *Ficus columnaris*, but which was supposed, but erroneously, to be identical with our *Ficus rubiginosa*. The late *Mr. Carron*, who had visited *Howe's Island*, and was well acquainted with its vegetation, gave me the following account of this remarkable tree, as follows:—

"Amongst the many plants peculiar to *Lord Howe's Island* is a very remarkable *Fig* tree, which the inhabitants call the *Banyan* from its mode of growth so much

FIG. 20.—LEAF-GALLS PRODUCED BY THE GRAPE-LOUSE (PHYLLOXERA). NAT. SIZE.

bling it in every line of colour; *Edward Morren*, *Alfred Colomb*, *Etienne Levet*, *Marie Rady*, *Marie Baumann*, *Princess Beatrice*, globular; *Chabriland*, *Baroness Rothschild*, unhappily so little fragrant; *Madame Charles Wood*, even though flat; *Charles Lefebvre*, *John Hopper*, sometimes quartered; *Gloire de Dijon* and *Malmaison*, globular in bud but expanded when full blown; *Triomphe de France*, flattish but with closely imbricated petals, and plenty of them; *Maréchal Niel*, model of the deep petalled *Teas*; *La France*, almost *sui generis*, in form perhaps is an improved *Cloth of Gold*, that most capricious of flowerers. *Madame Vidot* and *Madame Victor Verdier* and *Beauty of Waltham* are also shapely *Roses*. We purposely omit the *Paul Néron* class, because, like *Mantellini's Countess*, they have "no outline," or like that of the "*Duchess*," for the full description of whose outline we must refer the reader to the pages of the immortal "*Nickleby*."

A question of serious import to the future of the *Rose* is suggested by any critical inspection of *Roses* in large numbers, whether at shows or in the *Rose* grounds. It is, what is to be the style of our future flowers? Every year we appear to be tending more and more towards roughness of petal and raggedness of circumference, and fewer petals relatively to size.

pipped flowers like *Pansies* or *Picotees*, be set out flat and singly?—a mode which necessarily circumscribes the display of foliage, not the least adornment which Nature has provided for setting off all flowers. Granted that the horticultural mind is difficult to move in new directions, yet there are not wanting pioneers—witness *Mr. W. Paul's* extemporised *Rose* garden at the *Botanic* not so very long ago. *W. D. Prior.*

NOTES ON BANYAN FIG TREES.

A QUESTION has arisen whether there are other species of *Figs* which send down adventitious roots in a similar manner to those known as *Banyan* trees, found in *India* and elsewhere, and which become gradually elongated, increasing in firmness and strength, until reaching the ground they take a firm root, and become distinct trunks or supports to the parent tree. *Baron von Mueller*, of *Melbourne*, directed my attention to this fact by inquiring if I had observed this peculiarity of growth in the common *New South Wales Fig*, *Ficus australis* or *rubiginosa*. It has, however, often been seen in the *Moreton Bay Fig* (*Ficus macrophylla*). *Baron von*

resembling that of the *Banyan* of *India* (*Ficus indica*), although in the colour, size, and form of the foliage, as well as the fruit, it is very different, and more resembles in these respects *Ficus macrophylla*, a noble tree found in the dense jungles of the coast districts in the northern parts of *New South Wales* and *Queensland*.

"This tree covers a great deal of the flat land on the lower parts of the island, and is a very striking and picturesque object from the numerous columnar stems supporting the large branches, one tree forming quite a grove of fine glossy dark green foliage, the branches throwing out their adventitious roots in all directions, and which may be seen of all sizes, from that of a stout cord swinging in the air from 15 to 20 feet long till they touch the ground, when they immediately attach themselves, tightening and swelling rapidly, drawing nourishment from the earth towards the support of the whole tree or family of trees, for they are all attached unless a large branch is injured and becomes decayed through, when the detached portion forms a fresh grove on its own account, as it were. So quickly do these stems, formed from the aerial roots, increase in size, that it is sometimes difficult to tell which was the original trunk. In some instances they are very numerous, and as various in size from the recently attached root just beginning to increase in size on to 2 inches and up to 2 or 3 feet in diameter, and seldom much more, as the trunks never attain the size of those of *Ficus macrophylla* on the east

of Australia, but these latter never form the columnar stems from the aerial roots like the Howe's Island plant.

"By some error in the *Flora Australiensis* this Fig, which has been correctly described by Baron von Mueller, Government botanist, Victoria, under the name of *Ficus columnaris*, is confused with *F. rubiginosa*, quite a different plant in appearance, and found much further south.

"It may be that the specimens furnished to Mr. Bentham were without fruit, and the leaves below the average size, for the leaves very much resemble those of *F. macrophylla*, being often 6 to 9 inches long and 3 to 4 inches broad, with stipules 3 to 4 inches long, the fruit receptacles roundish or somewhat Pear-shaped and $\frac{3}{4}$ inch in diameter, while the leaves of *F. rubiginosa* are always much smaller, more ferruginous beneath, and the stipules are of a dull rusty colour and not more than half the length. The fruit receptacles also are very much smaller, scarcely $\frac{1}{2}$ inch in diameter, and of a different appearance; in fact, the whole plant, whether young or old, has a very different aspect from that of *F. rubiginosa*, and certainly more resembles *F. macrophylla* than any other Fig that I am acquainted with."

We remark in the Banyan tree that the inferior surface of the branches, which always show a disposition to extend in a horizontal direction, sends down a number of fibrous roots, which sometimes become fixed in the ground, and serve as props or vicarious trunks. This is by some considered a mode of propagation, and by it an endless succession of trees are produced; but this is not the precise fact, they may rather be considered as a provision for the adequate support, both mechanical and nutrimental, of the heavy and extensive branches of the parent tree. When these branch roots are implanted in the soil they resemble the trunk of a young tree, but have never I believe in any instance been seen to produce branches or foliage; they appear only to serve as props to the parent tree. This is exemplified in the account of a Weeping Willow in the kitchen garden of the old castle of Etlingen (*Gardeners' Magazine* for June, 1833), in which it is said that "the greatest curiosity in this garden is a Weeping Willow, planted in 1787, which was nearly thrown down by a storm in 1816. One branch was cut off, and an oak prop was put under the other. The Willow sent down a root under the decayed bark of this Oak prop, which, in 1829, being increased to about the thickness of a man's arm, burst from the bark; and it is supposed that in a few years it will render the oak prop superfluous." The Banyan of the Society Islands, named by the natives *Oró, Orá, Aóí*, has small, narrow, and lanceolate leaves, with a smooth or polished surface, while those of the Banyan of India are broad, ovate, and rough, green on the upper surface and downy beneath. *George Bennett, F.L.S.*

NOTES ON JAPANESE TREES AND SHRUBS.

PROFESSOR REIN, who has travelled widely in Japan, recently delivered a lecture on the vegetation of Japan before the Horticultural Society of Berlin, and we are indebted to the *Monatsschrift* of that society for the following extracts.

Of all the species of *Hydrangea* *H. paniculata* is the most widely dispersed in a wild state, ascending to an altitude of 5000 feet, where it forms large bushes. In many places it is used for paper making. The genus *Acinidia* comprises four or five species, all of which inhabit the mountain forests, climbing from tree to tree, to a height of 65 feet or more. The fruit of *A. rufa* and *arguta* is edible and eaten, being of a bitter-sweet taste, and by no means disagreeable. The fruit of *A. polygama* is not edible, but it possesses in a remarkable degree the power of attracting cats, and this property is common to the whole plant. This peculiarity is so marked that it has given birth to the proverb: "He sticks to it like a cat to a Matlabi." *Schizophragma hydrangeoides*, a shrub of climbing habit closely allied to *Hydrangea*, is also found in the mountains up to 5000 feet, and on account of its beautiful pure white flowers is highly esteemed.

To illustrate his remarks on the timber trees of Japan, Professor Rein exhibited a collection, of Japanese preparation, of 100 vertical and horizontal sections of Japanese woods, mounted in a kind of album on paper. The method of mounting is European, which the Japanese saw in the Exhibition

at Vienna in 1873, and the collection was made at the expense of the Government. The most noteworthy among these specimens is a number of differently coloured varieties of the wood of *Cryptomeria japonica*, the largest tree in Japan. This sometimes attains quite extraordinary dimensions; Professor Rein measured the trunk of one breast-high which was nearly 35 feet in circumference. *Retinospora pisifera* and *obtusa*, and *Thujopsis dolabrata* are trees of moderate size, occasionally with a trunk a yard in diameter. Professor Rein thinks there are only three species of *Pinus* native of Japan, namely, *P. densiflora*, *P. Massoniana*, and *P. parviflora*. The two first are favourite trees of the Japanese, and are represented in lacquer and on porcelain ware, and living specimens are found in nearly all gardens. Some of the latter are curiously distorted, and from 200 to 500 years old, and they are regarded with an amount of veneration bordering on worship. Some of them have very long horizontal branches resting on the ground. *P. Massoniana* loves a sandy soil, is harder and perhaps rather larger than *P. densiflora*, and consequently more generally cultivated. It forms magnificent avenues, its rich dark green long leaves being very beautiful. It attains a height of 100 feet, with a diameter of 6 feet. *P. parviflora* belongs to the group with five leaves in each sheath. It is widely dispersed in Japan, and reaches an altitude of 9000 feet, where it becomes shrubby. *P. koraiensis* is only cultivated in Japan. *Abies Tsuga* is extremely common in mountain forests up to from 5000 feet to 6000 feet, as also *A. polita*, *A. firma*, and *A. Alcoquiana*. *Salisburia adiantifolia* is not wild in any part of Japan, and is exclusively planted near the temples. The largest specimen seen by Professor Rein, which is regarded by the Japanese as the largest in the empire, measured nearly 23 feet in circumference, but it was scarcely 50 feet high. *Juglans mandshurica* and *Pterocarya sorbifolia* are the only *Juglandaceæ*. Among the *Cupuliferæ* Oaks are represented by twenty-two species, about one-third of which are evergreen. The latter are mainly confined to the southern parts, and probably do not extend further north than the Bay of Yeddo. About the town of Yeddo they are very much cultivated.

Forests of evergreen Oaks were only seen in the southernmost island, *Kiouson*. One species, *Quercus cuspidata*, has edible acorns, which, boiled or roasted, are offered for sale in the streets in winter. The wood of the evergreen species is regarded as better and tougher than that of the deciduous species, and is preferred for many purposes. *Castanea vesca* is wild throughout Japan; Professor Rein observed it in sixty districts. Beeches are abundant, and are of two species, *F. sylvatica* and *F. Seiboldii*. *Planera japonica* (*P. Kaki*) furnishes a most valuable wood, for cabinet furniture and turnery, of all the deciduous trees of the country. The wooden plates and dishes generally used are made of this wood, and it is universally affirmed that it never cracks. This tree, *Laurus Cinnamomum* and *L. Camphora* are the largest of Japanese trees, occasionally as much as 20 feet in circumference. *Buxus sempervirens* is exceedingly common in the south, and its wood is almost exclusively used for making combs. *Distylium racemosum* occurs only in the southern districts; it has a very hard wood, which is likewise used for making combs, and the bark is burnt and the ashes sent to the different porcelain districts, where mixed with the earth it is used as a glaze.

There are two species of *Ilex*, *I. crenata* and *I. integrifolia*. *Magnolia hypoleuca* furnishes a most important wood, and the ashes serve for rubbing down lacquered work. From the extremely fine-grained flexible wood the familiar elliptical bread baskets are made, and all sorts of thin lacquered ware. This *Magnolia* is a stately tree, with leaves about 10 inches long, arranged in whorls, giving the tree at a distance the appearance of a Horse Chestnut. It grows in the mountain forests associated with Beeches and *Esculus turbinata*, and trunks more than a foot in diameter are not uncommon. *Paulownia imperialis* is another example of a tree commonly cultivated which is not indigenous to Japan. The soft wood is employed in making shoes, and for making light boxes, in which the more fragile articles of lacquered ware are packed. *Erodia glauca* is rapidly disappearing from the forests, and is not yet cultivated. The inner bark is eagerly sought for dyeing silk of a yellow colour.

Six species of *Rhus* have been observed in Japan, though two of them, *R. succedanea* and *R. vernicifera*, are only cultivated, and originally introduced

from China. The cultivation of *R. vernicifera* and the collection of the lacquer is one of the principal industries of Japan. Some of the villages are completely surrounded by forests of this small tree. Like *R. Toxicodendron* and some other species, this is venomous to some, in fact, to most persons on first touching it; but it is averred that the same person suffers only once. Contact with the plant, or the lacquer it produces, or even inhalation of the vapour, causes the softer parts of the hands between the fingers, the tips of the ears, margins of the eyes, cheeks, scrotum, &c., to swell and inflame, and during four or five days the effects are very painful. The *Camellia* occurs wild as a shrub on the eastern side northwards to the Bay of Yeddo (36° N. lat.), and, strange to say, up to nearly 39° on the colder western side, where Professor Rein found it as underwood, rarely exceeding a yard high in hill forests up to an elevation of 800 to 1000 feet. Advancing southwards it is gradually larger, and in the southernmost island it is quite arborecent, though never so large as the largest cultivated specimens seen.

It is a noteworthy fact that Professor Rein found *Camellias* growing and flowering under Beech trees, with *Asperula odorata* carpeting the ground beneath. Many large cultivated specimens were measured, and some were found with a trunk $4\frac{1}{2}$ feet in girth, and over 30 feet high. Though not found wild so far north it succeeds up to 40° N. lat. on the western coast, where it is cultivated mainly for the oil furnished by the seeds, which is used for anointing the hair. With regard to *Broussonetia papyrifera*, Professor Rein mentioned that attempts were being made to cultivate this useful tree in Germany, on account of the dearth of material for the manufacture of paper. At his instigation 10,000 seedlings have been procured from France, and planted on the railroad banks near Frankfort-on-Main and Wiesbaden, besides 1000 young trees.

Other plants used for paper-making in Japan are *Edgeworthia papyrifera*, *Wickstroemia canescens*, *Aphananthe aspera*, and *Morus alba*. Paper from *Aralia papyrifera* is only made in Formosa. In answer to some enquiries, Professor Rein stated that *Wistaria sinensis* is wild throughout Japan, and not introduced, as Siebold affirmed, from China; it fruits freely. *W. brachystachys*, which was not found growing wild, may be a variety of *W. sinensis*. Miniature varieties of native trees were not observed, though artificially dwarfed specimens of numerous species are so largely cultivated.

CONCERNING PEAS.

THERE are so many new Peas, or at least assumed new varieties of Peas, putting in an appearance from time to time, that it is well some general conclusions can be periodically drawn concerning them in order that the horticultural body may know something of the character of the novelties so constantly being brought before them. I have just had an opportunity of inspecting a comprehensive proof of Peas at the trial grounds of Messrs. Hurst & Son, 6, Leadenhall Street, E.C., at Croydon, a trial so successful as to warrant fair average deductions being made as to the distinctness and worth of the newer introductions. The grounds are remarkably well managed; all new things are tested without favour or prejudice, and as something like 2500 trials of Peas, Cabbages, Kales, Carrots, Onions, Leeks, Lettuces, Beans, &c., have been made this season with the greatest care and attention, the comprehensiveness and thoroughness of the work is thereby demonstrated. Seldom has a trial ground appeared so clean, neat, and well ordered as this one at Croydon.

The wholesale seed trade is sometimes accused of carelessness in the matter of the quality of its stocks of vegetable seeds. This is not true of the firm of Messrs. Hurst & Son, for a sample of every bulk that comes to the warehouse is carefully tested, and its quality determined. All inferior stocks are at once rejected. These trials are calculated to inspire confidence, for the very best stocks are selected for seed purposes to grow from to supply customers. When trial samples are of good quality they are rigidly selected, and only the finest types saved. This is done year after year, and increasing business transactions attest to the confidence thereby inspired.

Of early Peas a fine stock of Improved Sangster's No. 1 was well ahead in point of precocity. It

flowered at the same time as Dillestone's, but beat it by three or four days in maturing its pods. Taber's Perfection has a darker green pod and haulm than Improved Sangster's, but proved as early. William the First must be set down as a remarkably fine early Pea, as early as Improved Sangster's, with a dark green pod and excellent flavour. Kentish Invicta proved early and good; the pod the same size and shape as Improved Sangster's, but of a darker green. Emerald Gem is early and a good cropper, with a taking bright shining green pod. First-crop Blue is a capital dwarf early Pea, producing good pods, and finding much favour among market gardeners.

Prizetaker has long been a good standard Pea because of its productive quality and handsome pods. Hundredfold, which much resembles a round form of Champion of England, is very like it in growth and general appearance, but rather more pointed and shorter in the pod. Laxton's Supreme beats both—a variety that is now generally cultivated.

Fillbasket is a very fine Pea, with large, bold, green, slightly incurved pods, and a great cropper; it grows to the height of 2½ feet, and is a first-rate main crop variety. Laxton's Prolific Longpod, the first of Mr. Laxton's seedlings put into commerce, is a somewhat puzzling Pea. When first grown after being distributed a mixed sample resulted, there were green pods of the Prizetaker type, and long white pods of the Dickson's Favourite type. Some selected the green form, and others the white form, which was the type Mr. Laxton intended, namely, an improved Dickson's Favourite. The green form reverted to Prizetaker. The samples at Croydon all represented the Favourite type, and very fine it was—the pods long and well filled.

Two new varieties, received under the names of Balmoral Castle and Market Garden Favourite, could not be distinguished from Supreme. Market Favourite is a great improvement on the old Ringwood Marrow, and makes an excellent market variety; it is a great cropper, the pods fine and well filled, growing about 4 feet in height. Allen's Champion, a new variety of the past year, is simply a good stock of Dickson's Favourite, and a second early.

The old Victoria Marrow, or Thurston's Reliance, is yet a good Pea, a great cropper, bearing well-filled pods. Berkshire Challenge appears to be a fine type of the foregoing. Young's Nonsuch is a large late Pea, perhaps one of the latest in cultivation; in a dry state the seed resembles that of Supreme, but is larger; it is so robust in growth as to appear a variety that will resist mildew. In general appearance and quality it comes very near to Ne Plus Ultra.

The Sugar Peas were here both tall and short, and there was Blue Prussian, Bedman's Imperial, and the old Scimeter—sorts that are now only partially grown but required in certain districts. Supplanter has large green pods when in true character, but shows a tendency to revert to a small green form, and will have to be rigidly selected. It grows about 2½ feet. A dwarf Pea, named Bijou, appears to be the same as Little Gem. The Shah is very similar in appearance to Alpha, but barely so full in the pod; the seed is white wrinkled, while that of Alpha is green indented. The last-named is a good early Pea, with small green but well-filled pods, a good cropper, and turns in quickly.

Advancer still holds a leading position as one of the very best early wrinkled varieties; and thoroughly the late Dr. Maclean must have done his work in that his seedlings maintain their character so constantly and continuously. Dr. Hogg has fine pods, but both light and dark in colour, the former prevailing, and something after Dickson's Favourite in appearance; it is however a wrinkled Pea. Wonderful was here a remarkably good variety, beating Climax hollow, 2 feet in height, and bearing large well-filled pods. Dr. Maclean is like Wonderful in appearance, but with a larger and more pointed pod. Here it appeared delicate, and was much affected with blight. Omega is a good late dwarf Ne Plus Ultra, fine pods and an excellent cropper. Premier is a remarkably good Pea, fine, well-filled pods, and crops well. East Anglian is very like Premier, but more robust in habit, and a great cropper. It is represented to be a dwarf Ne Plus Ultra, but lacks the characteristics of that variety; it will do well on moist soils. Standard is like Dickson's Favourite, but with a broader pod and dwarf in growth, about 2 feet. Best of All is very like Premier in appearance, but earlier and dwarfer and an excellent cropper.

Veitch's Perfection still remains as a fine type of

Pea; a pure stock of it, such as could be seen at Croydon, represents an almost perfect garden Pea. Hairs' Mammoth—the old type of it grown for so many years—is earlier, a good cropper, with fine well-filled pods. G. F. Wilson is a remarkably good Pea of this class, but it must be well selected, as it betrays a tendency to run out. Prince of Wales is a good white wrinkled variety, bearing plenty of well-filled pods. James' Prolific is a fine early variety in this class, the pods large and well-filled—a good exhibition variety. Popular and Quality will have to be discarded; under the most favourable conditions the pods are small. Huntingdonian is an Early Champion of England, the pod a little whiter, and fit to gather sooner. Commander-in-Chief appears an inferior form of Champion of England.

The old tall Green Marrow is yet a very prolific and good variety, and it is not to be wondered at that many of the old school of gardeners are unwilling to give up its cultivation. Prince Leopold is a fine large type of Pea, with large, round, white seed in a dry state, but not sufficiently distinct from Veitch's Perfection in growth. Magnum Bonum is a fine Ne Plus Ultra, the latter being seen here in admirable condition. Giant Emerald Pea has large, shining, bright green pods, and will be found very useful for exhibition purposes. It is of a tall growth, like Ne Plus Ultra. Lastly, Laxton's Connoisseur greatly resembles Ne Plus Ultra in appearance, without being so good.

A few varieties suitable for exhibition purposes will be found in William the First, Fillbasket, Supreme, Market Favourite, Dr. Hogg, Dr. Maclean, Veitch's Perfection, James' Prolific, Ne Plus Ultra, Prince Leopold, and Giant Emerald. R. D.

THE ROYAL GARDENS, KEW.

(Continued from p. 77.)

IPECACUANHA.—Dr. King reports that he fears this drug cannot be grown profitably so far north in India as Bengal, but that the secret of its successful propagation being now perfectly understood any quantity of seeds can be sent out. A quantity of the dried root has been prepared by Dr. King for use in the Medical College Hospital of Calcutta, and found to be quite as efficient as the best South American drug. The disadvantage attributable to the extreme slowness of the growth of this plant, and hence small annual return of root wherever it has been cultivated, must be met by a greater extension of the cultivation, as to which there should be no difficulty, seeing that the plant is increased with astonishing facility by ordinary cuttings, root division, or by merely pegging a leaf to the earth.

LIBERIAN COFFEE.—The demands for this plant (first grown in this country at Kew in 1872), which has excited the expectations of Coffee planters in all parts of the world to the highest degree, far exceed our means of supply. Now, however, that the function of this establishment in introducing the plant into the Coffee-growing districts of India and our colonies is amply fulfilled, and both the seed and plants are to be had from Mr. Bull, of Chelsea, and Messrs. James Irvine & Co., of Liverpool, as well of other firms, no further supply will be kept in Kew than suffices for exchange of specimens with other botanic gardens and correspondents. Mr. Hiern has examined the African species of the genus Coffea in preparing the Rubiaceæ for the forthcoming third volume of the *Flora of Tropical Africa*. He has determined the claims of the Liberian Coffee to be regarded as a distinct species, as was indeed the opinion of its scientific discoverer, A. Zeltius, and he has described it in the *Transactions of the Linnean Society* (second series, "Botany," i., p. 171, tab. xxiv.), under the name of *Coffea liberica*.

Amongst the numerous favourable notices of the plant which I have received I will content myself with quoting two from opposite sides of the world.

Dr. Thwaites (Ceylon) writes, under date August 29, 1876, "Some of the first plants of Liberian Coffee you sent to me have become large bushes, and are producing berries. These latter are of a large size, but they ripen very slowly, evidently from the want of a higher temperature, so I am distributing some plants in the low country and near the sea." In his report for 1875 he also expresses the opinion that though the plants have become affected with the leaf disease, "they do not apparently suffer here (Perade-

niya) from the Hemileia so severely as our ordinary Coffee."

In the Malabar District of South India the Liberian Coffee has also disappointed the expectations which its large and leathery foliage seemed to encourage of its capacity for resisting the Hemileia. Its more vigorous habit of growth may, however, enable it to bear without succumbing the ravages of this insidious parasitic mould.

Dr. Imray (Dominica) writes while this report is in preparation, "I am thoroughly convinced that the Liberian Coffee will in time take the place of our native Coffee, if I may so call it. I think you would be pleased were you to see my Liberian trees with their healthy vigorous branches and large dark green bright shining leaves. Many of the trees have blossomed and are still flowering, and a small crop of berries is coming on. The plant must evidently be very prolific. I count as many as fifteen or twenty berries, even more, in the axils of the two opposite leaves. . . . It appears to me that the new species of Coffee is peculiarly adapted to this island. So far as the temperature and rainfall are concerned, the climate approximates very closely to that of Liberia, from whence the plant comes. If the cultivation of Liberian Coffee is generally taken up in Dominica, as I think it will be, there is a future for this little country. There are thousands of acres of splendid Coffee land that might be cultivated in this island, with no fear of the 'white fly' before the eyes of the planter, for the Liberian tree bids defiance to its attacks. Indeed there is a very eligible field for settlers here with a little money in their pockets who wish to cultivate Coffee. It might be pleasanter and more profitable in the long run to set their faces towards the west, instead of the 'far east.'"

The suppression of this product generally in Dominica, which island once yielded the finest West India Beans, has been the subject of correspondence with the Colonial Office. This led to the mission of Mr. Prestoe, the Government botanist of Trinidad, to Dominica, with a view of reporting on the subject. Mr. Prestoe's report, which is in every way an admirable one, deals with all the vegetable products of the island in an exhaustive and most instructive manner, and in respect of Coffee it shows that the cessation of its cultivation was not due to the larva of a small moth (*Cemistoma coffeellum*), which can be extirpated from a plantation with great ease, but to causes which are far more general, affecting the well-being of the whole island, and especially to mismanagement on the part both of the Government and the colonists.

MAHOGANY.—Dr. King reports that the demand in India for seedlings of this timber-tree continues to be larger than he can meet. Supplies of seed have been procured from Jamaica and forwarded to Calcutta.

MONSTERA DELICIOSA.—Mr. Bernays, Vice-President of the Queensland Acclimatisation Society, writes to me, under date April 27:—"I am sure you will be gratified to learn that *Monstera deliciosa*, the first and only plant of which (as I believe) received in Australia was sent by you to this Society, has proved itself to be well adapted to our climate. It has fruited this year with great success at Bowen Park, and is pronounced by the most competent judges to be, as its specific name indicates, a really delicious fruit."

The following is a statement of the packets of seeds and plants sent out during the past year, and included in 342 consignments:—

TEA.—The establishment of Tea plantations in Ceylon, which date from about 1868, and to which I alluded in my report for 1873, is now a proved success. Samples communicated to Kew have been pronounced by experienced brokers as of very excellent quality.

OFFICIAL CORRESPONDENCE.—The communica-

tions, letters, and enquiries addressed to this establishment during the past year from Government offices at home, in India, and the Colonies, as well as from private individuals in all parts of the world, have been unusually numerous. This part of the work of Kew is fast becoming a distinct department, and already absorbs a large part of the time of the Assistant Director in giving it attention. I select from an immense list of topics which have come under our attention during the past year the following as of some general interest:—

AFRICAN OIL PALM FOR LABUAN.—A correspondence has taken place with the Colonial Office on the subject of the introduction of the *Elæis guineensis* from the west coast of Africa into the Island of Labuan. The great simplicity in the extraction of the oil, whether by mere expression (as in Old Calabar) or by boiling, and the value of the kernels as a

Burmese Cardamoms fetch a low price in the market compared with Malabar Cardamoms, and it was supposed that this might be due to the intermixture of the seeds of this plant with those of a spurious kind. It was, however, quite certain from their microscopic structure that the seeds sent were not those of *Elettaria Cardamomum*, and it was not improbable that they might belong to *Amomum xanthioides*, the wild Cardamom of Siam, but about which scarcely anything is known.

In this, as in so many other cases, the materials sent to Kew for an opinion were from a botanical point of view lamentably insufficient, and this was in this particular instance the more to be regretted because a scientific department like the Indian Forest Service might easily obtain such a series of specimens for transmission to England as would enable the whole history of the Burmese Cardamom,

DESIGNS FOR CONSERVATORIES.

HORTICULTURAL builders have to study not only the requirements of plant growers but of architects. Conservatories intended to form part of the features of a mansion should obviously be in accordance with the style of the building, and as these structures are primarily designed for show houses rather than for houses wherein to grow plants, their suitability to the latter purpose is for this point of view a matter of secondary consequence. The accompanying designs (figs. 21, 22), prepared by Messrs. Weeks & Co., show how well the horticultural builders can adapt their structures to architectural requirements. In the one case we have a conservatory in the style of Queen Anne (stupidly called the Early English style), while the other is a Gothic design of Middle Pointed style.

FIG. 21.—CONSERVATORY IN MIDDLE POINTED GOTHIC STYLE.

further source of oil and feeding stuff when imported into this country, appears to make this an industry extremely well adapted for Labuan and adjacent islands. I have taken steps to obtain seeds from Africa and also detailed information as to the method of preparation.

BALSAMOCARPON BREVIFOLIUM.—Our attention having been drawn to a new tanning material known as the Algarrobo of Chili, which appears to be of very high commercial value and far superior to Divi-Divi, a quantity of the pods (the part of the plant used) was obtained from Chili by the intervention of H. E. H. Rumbold, Her Majesty's Minister at Santiago. It was distributed immediately to the following places as likely to prove suitable for its growth:—Adelaide, Bahamas, Barbadoes, Bermuda, Brisbane, Cape of Good Hope, Gunesh Khind (Bombay), Lahore, Melbourne, Natal, W. Australia.

BURMESE CARDAMOMS.—A sample of these seeds was sent to Kew by the India Office for identification,

which at present is very unsatisfactorily known, to be entirely cleared up.

CASTOR-OIL IN BAHAMAS.—A correspondence has taken place with the Colonial Office on the subject of the cultivation of the Castor-oil plant in the Bahamas. Governor Robinson states that "the Castor-oil plant grows here as a weed, but no endeavour yet has ever been made to express the oil. Thousands of gallons might be exported from here annually." A supply of the best Castor-oil seed was obtained from Calcutta and forwarded to the Bahamas. Governor Robinson now reports: "The yield of this variety of the Castor-oil plant is, we should say, fully three times greater than that commonly found amongst us, the heads and the Beans themselves being very much larger than those produced by the native variety. As the East India plant can be cultivated quite as easily and readily as our own, and as it possesses such a marked superiority in the matter of yield, we hope to see it speedily and widely introduced into the colony, so as to supersede the indigenous kind altogether."

(To be continued.)

Notices of Books.

Tropical Agriculture; a Treatise on the Culture, Preparation, Commerce, and Consumption of the Principal Products of the Vegetable Kingdom. By P. L. Simmonds, F.R.C.I., &c. London: E. & F. N. Spon.

Upon opening this volume we are forcibly reminded of a work by the same author which appeared so long ago as 1854, under the title of *The Commercial Products of the Vegetable Kingdom*. This book, which contained an immense mass of valuable information on the cultivation of the principal useful plants, and of the preparation of the products derived from them, has long been out of print, and as no one in the meantime has taken the subject up, Mr. Simmonds has done well to prepare a new work of the same nature, though, as will be seen, under a different title. That there is great need for a book of this kind, even in a much more extended form, is evidenced by the fre-

quent and constantly increasing applications made to the Royal gardens at Kew for special information on the best modes of cultivation of valuable economic plants, together with the extended interest that is being taken in the acclimatisation of useful plants in different climates. A work that should include all that could be said, or, rather, all that is worth saying, on each product of the vegetable kingdom, would indeed be a ponderous volume, and, moreover, a very great undertaking nevertheless, such a volume, if carefully done, would be one of real value. What Hanbury has done for drugs in the *Pharmacographia* some other competent person ought to do for the other products of the vegetable world, and no doubt this would be done were it not for the one prevailing obstacle, namely, the expense incurred in publishing such a work, or the difficulty in finding a publisher who would undertake it. *Tropical*

3d. per lb.—remunerates the grower, who manufactures on a large scale." With regard to Tapioca, the fecula from the roots of *Manihot utilisima* and *M. Aipi*—the first known as the bitter and the second as the sweet Cassava, Mr. Simmonds says that of all the crops grown in Brazil it is the one that gives the best return and the least trouble. It is computed that at the lowest valuation the revenue derived from this culture would give a result superior to that derived from Coffee, Sugar or Cotton. Though a native of Brazil the Cassava or Tapioca plant has been introduced and largely cultivated in India and the Straits Settlements, besides being grown in considerable quantities in Guiana, the West Indies, and in some parts of Africa. From the fact that we get very large supplies of Tapioca, in the various granulated forms known in commerce, from Singapore, we can readily believe Mr. Simmonds that in Singapore

ture of starch by the ordinary process of crushing the root, washing the starch out, and decanting it, moderate-sized roots 1 foot in length and 1 inch in diameter are mostly used. The starch is of a fine colour, and has a most agreeable flavour; mixed with warm water it produces a fine transparent paste. The method of preparing the two other kinds of starch from the roots of the Dog's-tooth Violet and the Fern—the former of which merits special mention for its qualities—does not present any peculiarity. Both form articles of food, but the Fern starch is also used in various industries, as it produces a very strong paste, called 'shibu,' on being carefully mixed with the sap of unripe Persimmons. The fibres of the Fern root, after the starch has been washed out, are made into ropes, which are used in the mud walls of the buildings, so as to afford a better hold for the loam. It may be added that the manufacture of starch-sugar has long been known in Japan. Millet and Rice are used for this purpose, and after being steamed they are mixed with a certain quantity of malt or ferment,

FIG. 22.—CONSERVATORY IN QUEEN ANNE STYLE.

Agriculture is certainly an improvement as a work on *The Commercial Products of the Vegetable Kingdom*, though the title does not commend itself to us so favourably as that of the older book. The plan is in most respects similar. Thus, under "plants yielding seeds, leaves, and other substances employed in domestic use for the preparation of dietetic beverages," &c., are included cocoa, coffee, tea, and sugar, the latter from all sources, namely, cane, Beetroot, Maple, Palm, &c. Under the head of "Useful Palms and their Economic Products" is brought together much information on the varied products of a most important natural order. Section 3 is devoted to "Tropical Cereals and Starch-producing Plants." The importance of the cultivation in Queensland of *Maranta arundinacea*, *Canna edulis*, and *Manihot utilisima* is pointed out from the fact that the plants appear peculiarly suited for growth in the colony, and are "gradually supplanting the imported West Indian product in the Australian market; a very small price—about

the Tapioca manufacture has been very successful. The crop, however, is said to entirely exhaust the soil in five years. It is, moreover, startling to learn that as many as 10,000 cwt. of Tapioca and Arrowroot are shipped annually from Penang to Great Britain and the United States. A good deal of interest has been evinced of late regarding Japanese products, more particularly those used for food, we therefore quote the following paragraph relating to Japanese starches:—

"These are the 'Kudzu,' or starch made from the root of *Pueraria Thunbergiana*; the 'Kata-kuri,' made of the root of a kind of Dog's-tooth Violet (*Erythronium dens-canis*); and, finally, the starch prepared from the root of the Fern, *Pteris aquilina*. All these three plants grow wild, and the Kudzu, which yields the best starch, is very abundant in certain places. It belongs to the Papilionaceous family, grows very rapidly, and in a short time its creepers cover the ground, spreading over the neighbouring bushes and trees their luxuriant foliage. The root is frequently over 5 feet in length, and as thick as a man's arm. For the manufac-

and kept for several hours at a fixed temperature in close vessels, after which the liquid portion is strained and concentrated by evaporation to a strong syrup or a solid mass, which is formed into bars while hot. Vendors of this starch-sugar are often to be met with in the streets, when, to the great enjoyment of children, they manufacture all sorts of animals and figures with this material by a process quite similar to that of glass-blowing."

The foregoing extract will serve to show the character of the book, and it will suffice to say that the principal commercial dye stuffs of vegetable origin, the oil seeds and oils and the chief commercial fruits and spices, are subsequently treated of in like manner. With regard to botanical nomenclature we think the author would have done well if he had simply given the most recent or the generally adopted name of each plant without the synonyms; with the name once given the synonymy is easily traced back by a scientific man or one who has access to a good botanical library; and as the work is intended more for the use of planters and commercial men—amongst whom it will

no doubt circulate largely—simplicity and brevity in the botanical portion are recommendations. The value of the book, of course, is for its practical nature as a handbook or guide to intending planters, and as such it will no doubt fulfil its mission.

Florists' Flowers.

LARGE-FLOWERING PELARGONIUMS.—This is the time of year for cutting down plants to obtain cuttings. As soon as the plants have gone out of bloom they should be stood out-of-doors in a shady place to ripen their wood, and the plants should be kept tolerably dry for a time, both before and after the cutting down process. If the weather be fine, warm, and dry, the plants can remain out-of-doors till they are repotted; if, on the other hand, it be wet and dull, the plants will be best in a cold frame, with the protection of glass and plenty of air. In cutting down plants it should be so performed as to lay the foundation of a good level bottom, likely to yield a symmetrical growth. The well-ripened growth of the current year makes the best cuttings. They strike well in a spent bed, which has been used for raising Dahlias from seed or Cucumbers, to put out in lines in some sandy soil; in this they soon root, and should then be potted off singly into small 60-pots. Nurserymen who do a large trade with Pelargoniums send out the majority of their plants in the autumn, therefore there is urgent need for getting the cuttings rooted as quickly as possible. As soon as they are established in the 60-pots, and commence to grow, the leading shoot should be pinched out rather low down, which causes the plant to break into side growths from the lowermost eyes; in this way young plants with good bottoms are formed. At this stage the plants do best on a high shelf in an airy position, near the glass.

When they again start freely into growth a shift will be required into 48-pots, and in these the plants can be distributed when fully established, or wintered for sale in spring. By judicious stopping young plants with four and six, and even more leading branches can be obtained, and these, if kept in 48-pots, make excellent decorative plants when in bloom.

Cuttings can also be readily struck in well-drained pots or in shallow boxes, placed on a warm shelf in a greenhouse; but in all cases they prefer warmth to cold. They may be struck all through the winter if put singly into small pots as fast as cuttings can be obtained of any choice or scarce varieties.

The cut-down plants should not be repotted till they commence to break forth into fresh growth; and when the shoots are an inch long, the plants require to be turned out of the pots, all the soil shaken from the roots, which should be reduced by trimming away the long main ones, and then repotted in smaller sized pots, and placed in a frame or greenhouse and kept close for a few days till established in the soil, and then they may have an abundance of air to induce a sturdy growth. The final repotting into the flowering pots should be made at the end of September or early in October. *R. D.*

Apiary.

MASSACRE OF DRONES.—May I now remind beekeepers that the time has come round when the question which I mooted last autumn—whether the bees really did massacre the drones or not—can be authoritatively settled? Within ten days or so the so-called massacre will take place. If any one with an empty observation hive will now put food in it, then sweep into it a good supply of drones without any workers, and keep them prisoners there for a month, the question may be put at rest. If they die off of themselves, then the massacre is a fable. If they live, then it is probably true. *Andrew Murray.*

Garden Operations.

PLANT HOUSES.

PLANT STOVE.—Gardenias will furnish flowers for many months where a sufficient number of plants are grown, and these receive treatment such as necessary to bring them into bloom in succession. Where they are so required, it is well to propagate some young stock every spring, as also to employ some that are older and larger. From their natural free habit of growth, when kept for any length of time, unless freely cut back after flowering, they soon acquire a size that renders them not nearly so convenient to manage as when smaller. The latest flowered old plants, now cut-in, have yet plenty of time before the end of the year to make enough growth, after which they will again come into bloom the latest next summer. Immediately they are cut back, give them a thorough cleaning with insecticide, stand them in a brisk heat, and when they have broken into growth turn them out of the pots, remove a portion of the surface soil without mutilating the roots more than can be avoided, and put them in others a size or two larger. There are those who advocate planting out Gardenias and some other subjects of a similar nature in preference to pot culture. This system may answer with those who grow for market, and do not object to having a whole houseful of any one thing blooming at the same time, but in private establishments this planting out with anything but Camellias is a very great mistake, as under the system there is no chance of varying the treatment so as to give a succession of flowers; and with growers for sale as well as private places there is a very important matter lost sight of, that is, the facility for cleaning them from insect pests, which with these in common with most stove plants involves a serious amount of labour. When such things are planted out, there is no chance of keeping down scale, or mealy-bug where it exists, without a continuous use of sponge and brush, whereas a plant in a pot can be taken and either dipped in insecticide, or laid on its side and syringed, by both of which methods as much work can be done in an hour, and far more effectually, than can be got through in six by hand-sponging. Those who advocate planting out, say the plants grow quicker than in pots, but if stove subjects are well managed there is no difficulty in inducing them to make as much or generally more growth than is needed. *Euphorbia jacquiniiflora*, especially the latest struck plants, will often run away with a single shoot if not stopped, but shoot-pitching, with this plant, must not be continued too long, or it will interfere with its blooming capabilities: the beginning of August is as late as the operation should be performed. A few more plants of *Eucharis amazonica* that have fully matured their growth should be subjected to a resting process, by withholding water till the leaves flag slightly, after which give a little, and again let them get dry, repeating this for a few weeks, which will prepare them for flowering when submitted to a little more heat with the full quantity of root moisture. This easily managed plant will afford almost a continuous supply of flowers where a sufficient number are grown and induced to make growth at different periods, and then subjected to the above treatment at intervals. The last sowing of *Celosias* should be pricked off in small pots and encouraged to grow. The natural disposition of the plant to spire up tall and thin may to a considerable extent be corrected by growing them near the glass, with abundance of light and sufficient air. They will also bear stopping whilst in a young state, which will cause them to assume a more bushy form. I have no doubt the tall habit of growth possessed by these *Celosias* might in time be corrected by selecting seeds from any that showed a dwarfer disposition. For some purposes, such as conservatory decoration in summer, tall plants can be used with advantage, as they relieve the even surface of lower growing things, and although most useful as late autumn-flowering subjects, yet their distinct habit, and the extremely bright tints of the higher-coloured examples render them most serviceable summer decorative plants. Successionally flowered *Amaryllis* that have now completed their growth must be fully exposed to sun and light, and have water gradually withheld with the deciduous kinds. This on no account must be done until the leaves are thoroughly matured, or they will flower unsatisfactorily, or not at all. The evergreen section ought also to be kept much drier, but water must not be withheld, so as to cause the leaves to flag. Plants of *Clorodendron fallax* and *C. Kæmperii* are more useful as decorative subjects in a small state than when large. There is no better method of securing them in this way than from seeds. Such as flowered early, and were allowed to mature seed, will by this time have them ripened, in which condition they are easily distinguishable by turning quite black, and parting from the capsules with a slight touch. They should at once be sown singly in small pots in sandy loam, placed in heat, and kept slightly moist. So treated they will very soon vegetate, when they should at once be stood close to the

glass, to prevent their being drawn up weakly. In the autumn they should be shifted into 5-inch pots, and kept growing slowly in the stove during the winter. If moved in February into 9 or 10-inch pots they will make nice blooming plants next summer. *Ardisia crenulata*, the berries of which are now swelling, should have plenty of light and enough warmth to keep them growing freely. Syringe the plants overhead to keep them clean. They look much the best when grown in pots small in proportion to the size of the plant; but when so treated, to insure the leaves having the dark green glossy appearance without which, however well furnished with berries, they possess little beauty, they ought to have weak liquid manure given them once a fortnight or so. Of *Æschynanthus* grown in baskets—than which there are few more appropriate or effective plants when fairly treated—autumn blooming kinds, such as *Æ. grandiflorus*, must have their requirements as to water sufficiently attended to or the flowers will fall off before they expand. Suspended plants of this description are much more liable to get neglected than such as are more immediately under the eye. Where Palms, the most elegant of all subjects for table decoration, are grown, a continuous supply of small stock should be yearly added, as they soon get too large for the purpose. Some of the more beautiful kinds, such as *Cocos Weddelliana*, are now plentiful and cheap. This, with *Chamedorea graminifolia* and *Areca lutescens*, are, from their natural habit, particularly adapted for employing in this way.

HARD-WOODED GREENHOUSE PLANTS.—Heaths.

—Any of the early spring-flowering varieties that after blooming have now made some growth and are wanted to flower early the ensuing spring, say in March or April, may be stood out-of-doors at once, but where not required in bloom until May their full exposure should be a little longer deferred, as the earlier they are turned out the earlier they will flower. Autumn blooming sorts—the best of which for either general decorative or exhibition purposes are, *Marnockiana*, *Austriana*, *Irbyana*, *retorta major* Jacksoni, and *Turnbullii*—may now where desirable have their time of flowering considerably retarded by standing them in a north house where they will get plenty of light but which by its position, through being less exposed to the action of the sun, is much cooler. Such a house not being available, they will do on the north side of a wall in an open situation, with lights temporarily fixed over them. Any retarding operations of this kind are much more effectual, and less calculated to injure the plants when carried out thus early, than when an attempt is made to keep them back when the flowers are further developed. Camellias will now require attention. Where a sufficient number of plants are grown to afford a succession of flowers, from October or November, until late in the spring, it is essential to look well ahead during the growing season. Plants that bloomed about the above time last autumn, and were after flowering placed in a little warmth to encourage growth, will by now have their buds in a forward state, and should the weather continue very hot it will be necessary to see that they do not come too early. Where there is any danger of this and the plants are planted out in beds, there is no resource but keeping the house wide open night and day with all the air possible, and shading with mats, which will have a deal of influence in keeping down the temperature. Plants grown in pots and in a similar condition, should at once be moved to a north house, or stood on the north side of a wall, with temporary lights overhead to guard against heavy rains, or with a canvas covering attached to a roller and supported by a light frame-work that admits of its being let down when there is an appearance of thunderstorms. The framework in question carrying a blind of this description should be fixed at an angle of not less than 45°, otherwise the water will drip through the canvas instead of running down to the eave. With Camellias that, on the other hand, are required to bloom earlier than they have hitherto done, the present is the time to regulate this, as by keeping them in a house or pit that is directly under the influence of the sun with only slight shading to prevent their leaves scorching, and partially or wholly closing in the evenings, the flower-buds will now fast increase in size, and the time of their expansion be much accelerated. Any that are at all affected with either brown or white scale, but especially the latter, even if well cleaned before growth commenced, should again be gone over, removing it from the buds and all round their base, where this pest generally establishes itself; but in doing this care must be taken not to subject them to any rough usage. *T. Baines.*

ORCHIDS.—In some cases *Dendrobium nobile* may be so managed as to bloom in the winter and spring on growths made during the summer previous; the more natural and regular course, however, is for the blooms to appear on the bulbs that are two seasons old. *D. chrysothrix* is in many respects very different to the foregoing, and flowers on spikes from the bulbs, whilst the growths have the leaves fresh and green, and the

young shoots still growing vigorously. When the plants of this are resting during the winter months the growths retain their leaves, and the points of the bulbs indicate a growing tendency, so that when the growing season commences the shoots start away again from the top, as well as start new breaks from the base of the bulbs. The flower-spikes, to the number of from three to six, appear along that part of the bulb formed during the previous summer. This is one rather more difficult to grow than many of the others, but in the Dendrobium-house, with the temperature regularly kept as advised, it will generally grow very freely and satisfactorily. It may be grown both in pots or in baskets; in the latter the blooms appear more regular and numerous, which perhaps may be accounted for by the fact that the plants receive more light than those grown on the stage. Being naturally of a straggling habit it should have several sticks fixed in the pot or basket, and as the young breaks start away tie them round, and continue to tie them round as they increase in length. By this means the plants are more compact, have a more pleasing appearance, and when in flower the mass is much more effective than the spikes would be if the bulbs were hanging about in a loose and straggling manner. Dendrobiums on blocks must now have an abundance of water; if they are hanging in such positions that the syringe can be used without the fear of drip endangering those that are under or about them on the stage, let them be sprinkled twice a day—this will help to keep them clean, as well also as being a watering for them. If, however, they cannot be treated in such a manner with safety look them carefully over, and dip them as often as they are in any way dry, which will with many necessitate their being taken down every morning.

Cypripediums, whether of the barbatum or the Lowii or Stonei type, almost invariably flower in the spring, and few plants retain their blooms in a state of freshness and beauty for such a length of time as these. Blooming generally very freely, and at the same time producing such singular forms and pleasing contrasts of colour, they are always attractive and objects of peculiar interest. The remaining flowers of these must now be all taken off, and if placed in water they will last as long as if they were on the plants. Any that have got green or sour on the top of the soil must have the sour part picked out, and the plants surfaced with a mixture of peat and moss and a few broken crocks. The new roots now starting away will readily take to the new soil, and materially assist the new growths that are now or that will shortly be pushing up. Whilst in flower these make little or no growth, but that period being over the plants start growing, and continue so doing the whole of the season until the time of the flower-spikes showing again. A good share of water must at all times be given, the greater quantity, of course, when the roots are in a healthy condition, and whilst they are growing vigorously a sprinkling overhead in the afternoon will be found to be very beneficial. *C. Schlimii*, *caudatum*, and *Sedeni* must be grown in the Cattleya-house, requiring less heat than many of the others, but on no account must the supply of water be lessened. *W. Swan.*

FLOWER GARDEN, ETC.

Special attention is now required in the flower garden and pleasure ground, and now that the plants are advancing and filling up their places the regulating of their shoots must be carefully looked to. Most of the beds are very well filled, and the plants blooming nicely. The strong growers should be kept in their places should they show a tendency to extend beyond their proper limits, and weak growers that would be improved by a slight stimulant may have a little liquid manure to assist in making up lost ground. Keep all decayed flower-stems picked off, and remove all leaves as they become unsightly. Vase plants must not be neglected—give them a plentiful supply of water, and those that are blooming freely may have liquid manure twice a week; this treatment will soon have a visible effect. Roses had better be looked over frequently, as the showery weather spoils their flowers often before they expand; this is a good time for budding, which may be done at any leisure opportunity—the buds I find are in good condition. Pelargoniums are growing freely, and will soon require thinning-out; and the season for preparing a stock for next year is almost at hand. It would be advisable to get suitable soil in readiness for the occasion, light loam mixed with sand suits admirably. I find that rough boxes, about 30 inches long by 12 inches wide and 4 inches deep, which any handy garden labourer can make, are the most convenient for Pelargoniums; the boxes pack well together, and a large quantity of plants can be accommodated in less room than by any other mode that I am acquainted with. Pelargoniums are all struck in the open air. Attend to tying and training plants as they advance; those that require pegs must also be looked to. Take every opportunity after showers of having the walks well rolled. Keep weeds down by every possible means, and have the grass always in the best keeping. *T. Blair, Shrubland Park, July 24.*

HARDY FRUIT GARDEN.

The severe check Peaches and Nectarines received during the early stages of their growth has caused them to send forth many laterals, all the best situated of which it will be necessary to lay in, as little bloom can be expected from the main shoots, so gross and watery are they in their character. Even were it possible to get them ripened, of which there is little chance unless the autumn should prove unusually favourable, it is very rare that they are at all fruitful, and except for the purpose of filling vacant spaces or forming the foundation of a future tree they are seldom worth preserving, and should either be stopped back when they first show or removed altogether. In the case of young trees where the object is to get them thoroughly established and the wall covered as quickly as possible, such shoots are not objectionable, as they cause a rapid formation of roots, and by laying in any laterals they make on the upper side fruit may generally be obtained from them after having made one season's growth. I have adopted this practice for years both indoors and out, and never shorten back any shoot till the trees have furnished the allotted space, which I find they do in half the time it took under the old system, that still prevails in many places. As the season now left is but short every encouragement should be given to expedite growth, and make up for lost time, which may be done by plying the garden engine every evening after a dry hot day and keeping the borders mulched and duly watered, particularly where any trees have been recently transplanted, and have not, therefore, been able to penetrate far down in search of moisture. Want of this at the roots is one of the chief causes of the decrepid state Peaches and Nectarines often get into, especially when they have a little fruit to carry, as they soon become exhausted and a prey to red-spider, a pest that is sure to attack them should the flow of sap not be equal to the demand, as is the case whenever the borders become the least dry. Apricots are unfortunately in a very gappy condition, owing to the quantity of wood that has died out since the spring, and in regulating and thinning-out the growth of these due provision should be made by leaving such shoots as are well placed on the upper sides of the branches to get all vacant spaces properly filled in, which from the rapid progress most trees are now making there will not be much difficulty in accomplishing. In order to let in all the light and air possible to aid in the perfect maturation of these strong shoots and induce a free formation of flower-buds, all breast-wood should be kept closely stopped back, as after this there is no fear of them starting again. The same remark applies to both Pears and Apples, which will now require a final look over for the same purpose, for although fruit may be scarce it is necessary to render equal attention if a supply is to be looked forward to next season. Considering the deficiency of this useful commodity every effort should be made to preserve what we have to as late a period as possible, which in the case of Warrington Gooseberries, red and white Currants, may be done to at least the middle of October by securely netting them up, as from all appearances there will be no wasps to devour them. The best plan of keeping the above fruits is to plant at the foot of a low wall having a northern aspect, where they come later and keep in a fresh, plump condition longer than they do in a more sunny exposed position, and being all together they can be protected much easier than when bushes are standing about in isolated positions. The late rains have been very favourable for setting free the bark of all fruit stocks, which may now be budded with every prospect of success if the operation is carefully carried out. The principal thing is to see that the buds to be inserted are fully developed, and in taking them off and removing the wood cut away with them, the rind must not be turned back or bruised in any way, or failure is inevitable. Any shoots in which buds are inserted should be left to grow at full length, so as to draw the sap, but others may be cut away, which will force increased strength into those remaining, and thus render them better nurses to aid in effecting a union. *J. Shepard, Woolverstone.*

FRUIT HOUSES.

FIGS.—The second crop of these will now be making rapid progress. If not already done, let the fruit be moderately well thinned before the ripening period; until this term arrives let the roots have copious supplies of moisture, and the tops likewise, by means of the syringe once or twice every day, and, moreover, keep up a brisk moist temperature in the house constantly afterwards. When indications of ripening are visible substitute for the foregoing conditions those of a drier and more airy nature. Give regular attention to the stopping, tying, &c., which is needful, and by all means avoid a crowding together of the growths, as every ray of sunshine and light is now indispensable to harden and consolidate vigorous shoots, the points of which should be permitted to crop up above the trellis, where more air, &c., will naturally abound. Where additional stock has been made by means of

cuttings or layers such plants should be advanced by repotting, or as otherwise may be deemed best. In such cases, after the plants are first established in pots, we consider planting them out until they have made good-sized plants, and then taking them up and repotting them, preferable—inasmuch as a great saving of time and attention is effected, and satisfactory results are not thereby endangered. Give any trees which may be in pots liquid manure at least once or twice a week, and protect the surface roots of such trees by surface mulching. *G. T. Miles.*

THE CHERRY-HOUSE.—Cherry trees which are subjected to forcing operations annually are very apt to flower prematurely and make a corresponding growth—a fatal consequence as concerns the succeeding crop of fruit. To check any tendency in this way it is important that the leaves be kept on the trees as long as possible; for this end it will therefore be necessary to keep them free from all destructive pests, and to supply air most liberally constantly. If the structure consists of movable sashes remove these entirely, at once, and contrive even under these circumstances to ply the syringe or engine over the trees twice every day, and occasionally, if necessary for the purpose of destroying any insects which may abound, an application of strong quassa or tobacco-water should also be given. These means are likewise applicable to those trees in pots, which should now occupy an exposed place outdoors, where watering, &c., should be constantly seen to. If any doubt exists as to the condition of moisture about the roots, the fact should be ascertained and the means necessary used accordingly. Weak liquid manure or gnano-water applied now will help to stimulate weakly trees or such as have borne heavy crops of fruit. Cease to syringe Plum trees when the fruit begins colouring, and give them plenty of air in order to gain colour and flavour. These can be kept on the trees for a considerable time in a fresh state if they can be removed to an airy and shady place and be kept free from damp. *G. T. Miles, Wycombe Abbey.*

KITCHEN GARDEN.

By the end of this month or early in the next a liberal sowing of Cabbages of favourite sorts to stand through the winter should be sown. Of these we use three sorts—Veitch's Improved Atkins' Matchless, Heartwell Early Marrow, and Cattell's Reliance, besides our own sort, which has been saved in these gardens for over forty years, and is still scarcely excelled by any of the newer varieties. A good breadth of June-sown Cabbages should also be got out at once for autumn use, also that delicious vegetable the Conve Tronchada; this should during growth be treated to a little stimulation, as its great delicacy of flavour depends much on a free and succulent growth. Persevere in surface stirring with small narrow hoes amongst the advancing crops of Carrots, Onions, red Beet, and Parsnips. See that the late Peas are mulched with litter, to retain moisture; and bearing crops, both of Peas, Scarlet Runners, French and Broad Beans, should be kept well gathered as they become fit for use, as the perfecting of seed is a very exhaustive process and tends very much to reduce the amount of late crops. Capsicums and Chillies at the foot of south walls will need every encouragement to induce them to perfect fruit in time to ripen, and the foliage may be thinned out with advantage in order to assist the process. The same remark will apply with equal or greater force to Tomatos against walls, which should never be left overcrowded with foliage. *John Cox, Redleaf.*

PEONIES FOR SUMMER BEDS.—There is a genus of ornamental plants belonging to the Ranunculaceæ that come in early and flower freely, especially in the southern and western counties, and which is famed for its intense blaze of bloom, which I succeeded so well with in Devonshire that I would fain see it more freely planted—I mean the Peony. Most of the varieties grow a little over a yard in height, and may be confined by invisible wire, invisible only at a chain's length. Some of these Peonies were highly fragrant, and all of them gaudy, surpassing the Hollyhock and Dahlia in intensity of colour. There were in my time some thirty or forty varieties, and since that time they have had many additions. A clump or bed of Peonies requires to be made as deep and as rich as if it were a Vine border, for, owing to their tuberous roots, they cannot be regulated or manured easily after planting. *A. Forsyth in "Florist and Pomologist."*

"THERE'S a Rose looking in at the window,
In every condition of life—
In days of content and enjoyment,
In hours with bitterness rife.

"Where'er there's the smile of a woman,
As bright as a beam from above,
'Tis the Rose looking in at the window,
And filling the dwelling with love."

P. M. James.

THE
Gardeners' Chronicle.

SATURDAY, JULY 28, 1877.

APPOINTMENTS FOR THE ENSUING WEEK.

FRIDAY, AUG. 3 { Rosendale Floral and Horticultural Society's Show (two days).
SATURDAY, AUG. 4 { Southampton Horticultural Society's Show (two days).

THERE are flower shows at which the chief elements are the productions of wealth and professional skill, and there are FLOWER SHOWS where the exhibits are the products of poverty and perseverance under difficulties. In general character and in influence the results of these are widely dissimilar, as the former illustrate the enjoyment derivable by the wealthy from the pursuit of horticulture as a luxury, whilst the latter form the practical exponent of the struggles of the poor in their efforts to secure even but a small portion of that benefit that the pursuit of gardening invariably brings to all who follow it. We have often to listen to stale platitudes concerning the moral and social good that follows the spread of horticulture amongst the masses, but such platitudes, nevertheless, have the charm of truth. Horticulture is of all arts the one that admits of being reduced to a practical use most readily and generally, indeed thousands are as successful horticulturists, evidently devotees of art, without having the slightest knowledge that they are standing upon such elevated ground; the love for its practice is innate and is drawn out as by a process of evolution. Think as we may of the story of the old gardener ADAM, it is impossible not to feel that, whatever we may inherit from his failings, we at least, as human beings, never have and never shall fail to show that we inherit his love for horticulture, and taste for the useful and the beautiful in gardening.

Two exhibitions of horticultural produce held lately in diverse places, and under diverse conditions, afford evidence how strongly gardening has its hold upon the poor. In the one case a show of plants grown under the most adverse conditions by the humble denizens of narrow streets and crowded courts of the City; in the other a really remarkable display of what the industrious poor can produce from their allotments and cottage gardens in a suburban district where the surroundings are much more favourable to plant life than in the City, but yet scarcely so favourable as are to be found in the strictly rural districts. The City gathering, held in that most remarkable city garden of Finsbury Circus, shows in its broadest light the pursuit of horticulture under difficulties. The one, two, or three plants that represent the window-gardens of the poor exhibitors would hardly find a place in any ordinary greenhouse in any ordinary garden. They are clean at least, and indicate no lack of care, but they are mostly common, and where not so are scarcely so good as where the sorts are of the hardier, and therefore easier-grown species. What, however, most strikes the observer is the singular fondness—we might well say love—that appears to exist in the breasts of the owners for their humble exhibits. Shut up for weeks and months together in the middle of the great desert of bricks and mortar, and so far exiled from the charms and delights incidental to a rural life, these small plants of Musk, Stonecrop, Ferns, Fuchsias, Creeping Jenny, Orange tree, or sickly Myrtle, present to their owners the only tangible evidences and reminders of the great world of Nature outside — they keep alive in these pent-up bosoms thoughts of trees and grass and flowers — of parks, fields, and green leaves;

and wherever this feeling is found — this hankering after the delights of a rural life—there is raised a barrier against vice and immorality, against hatred and malice, against drunkenness and crime, against an utter oblivion of all that is good. When at the presentation of the prizes to the delighted winners during the day the Duke of WESTMINSTER responded for his amiable and popular Duchess he laid much stress on the desirability of converting even the spare spaces in disused churchyards within the City precincts into gardens, in which even in a humble and necessarily restricted way the poor might find additional stimulus given them to seek for relaxation and elevation in the more frequent contemplation of the beauties presented in the growth of trees, plants, and flowers.

What is seen in the way of a beautiful city garden in Finsbury Circus—a garden, we are sorry to say, too seldom open to the poor—might be seen in many other spots did not the mammon of wealth insist upon the conversion of every available piece of land into building sites. The churchyard of St. Botolph in Bishopsgate Street is a powerful evidence of what can be done to convert city churchyards from dismal, ghostly enclosures, morally and socially plague spots in the midst of teeming life, into pretty and joyous gardens, where old and young love to linger and spend happy hours. A venerable clergyman, speaking to his neighbours at Ealing, alluded to the singular influence that horticulture was capable of exercising upon the social life and mental growth of the people, and said that, at least in that great parish, no such frightful examples of facial development could be met with there as the great painter, HOGARTH, had portrayed a century since. He attributed this change to the gradual influences being so beneficially exercised on social life by social improvements, and specially upon the elevating pursuit of gardening, holding, as he did, that none could continue to cultivate, in ever so small a degree, the plants and flowers which beautify this earth without being insensibly but surely cultivated also. This is no doubt true, for all who come within the charms of its influence feel that gardening makes none of us worse, and myriads better than they otherwise would be. The show of cottagers' produce displayed at Ealing, evidences the existence there of a strong utilitarian spirit amongst the poor in addition to the not less active feeling of an æsthetic kind. Profitable garden products, whether vegetables or fruits, are specially attractive in the home where there are mouths to feed and bodies to keep healthy, whilst labour in the garden or allotment in the spare hours not absorbed in the ordinary toils of life becomes, not labour or toil in its restricted sense, but rather recreation of the purest and most exalted kind, leading on to a feeling of ennobling independence, and serving the humble purpose of assisting to promote materially the health and contentment of the family. Many years of continued stimulus and example have served to produce at Ealing the most successful results amongst its cottage poor in relation to their garden work. In addition to the prizes annually so liberally offered by wealthy ladies for the best gardens or allotments, the Society and its numerous friends present for the cottagers' competition, either in useful articles or sums of money, nearly 180 prizes, and the entries are so large that, as a rule, the prizes might be taken twice over. It is thus evident that the cottage element at Ealing is a singularly large one, and the spirit of emulation abroad amongst the poor is one productive of the happiest results. It is not the least excellent feature that not only are all the prizes largely contested but what will commend itself most favourably to the practical horticul-

turist is the undoubted fact that the produce shown is invariably amongst the best to be seen at any similar exhibition. It is good work well done when, in addition to elevating the moral faculties and improving the social status of the poor, it is also possible to make them, as cultivators of the soil, producers of vegetables, fruits, and flowers of the greatest excellence. The Ealing promoters of these results may well feel a pleasant glow of satisfaction, and thus realise a true reward for such well-meant, and, in this case, not valueless efforts.

Insensibly almost, but yet surely, gardening in its least technical features is exercising a marvellous influence for good. See on any public holiday, or on Sundays, when toil is no longer binding, how the people of all grades flock in myriads to the parks and public gardens that the first portion of the second half of the nineteenth century has brought into being. To take stock of what has been done by horticulture for the people in that short term of years would fill a volume—how many will be required when the century is counted out? It is with a feeling of profound satisfaction that gardeners survey the progress of their special art, and realise that amongst the many ennobling influences at work on the human family horticulture is playing a distinguished and a successful part.

— IN reply to very numerous enquiries, we beg to repeat that the ROSE SUPPLEMENT, with the coloured plate, presented to our subscribers with the number for July 7, is out of print, and will not be reprinted. We shall shortly issue a coloured plate of fruit, of which due notice will be given.

— In order the better to put our readers on their guard against the COLORADO POTATO BEETLE, we now give an illustration (fig. 23), from specimens kindly placed at our disposal by Mr. ANDREW MURRAY. We have nothing further to add to what we have repeatedly said as to the best means of coping with this new enemy.

— A correspondent informs us that a most happy effect was produced at the Royal Italian Opera, Covent Garden, last Friday, by a SHOWER OF BOUQUETS in honour of Mdle. ALBANI. The opera of "Lucia di Lammermoor" was selected for Mdle. ALBANI's benefit; the "unhappy bride" sang and played her part with the consummate power and skill which never fails to enrapture her audience. A heavy fire of flowers was opened at the end of the first two acts, there was no lack of ammunition, and at the end of the mad scene a general bombardment of bouquets from the audience completely covered the stage. Mdle. ALBANI was repeatedly recalled to receive this testimony of gratitude and good wishes, and the happy way in which she acknowledged her friends' compliments and gathered up her trophies was certainly not the least graceful part of the performance.

— One of the most remarkable events in connection with the recent show of the Royal Agricultural Society of England at Liverpool was the editing, printing, and publishing of a daily newspaper in the open air. The special daily edition of the *Agricultural Gazette*, thus brought out, had each day, in addition to the ordinary daily news of the showyard, one or more descriptive articles on the progress of agriculture, in its various branches, since the last meeting of the Royal Agricultural Society at Liverpool in 1841. Of this paper, which consisted of thirty-two pages each day, 30,000 were sold at 2d. each in the showyard. We are pleased to state that the venture resulted in a great success for our enterprising contemporary and former yoke-mate.

— The *Australasian* describes the following method of replanting the Government reserved land at the base of the Never-Never Range, which we borrow from the *Chronique de la Société d'Acclimatation de France*. Instead of sowing in drills or broadcast, as is usually done, pieces of Bamboo reed are employed. Thousands of pieces from 1 to 1½ inch in diameter are carefully cut to the uniform length of 4 inches. They are then stacked as closely as pos-

sible on end in square holes in the ground, their tops being on a level with the surface. A prepared sifted compost is thrown upon them, filling the tubes and the interstices. Two or three seeds are put into each tube by hand. This operation, although tedious at first, may be performed with great rapidity after a little practice. When the seeds have germinated and the young plants are sufficiently advanced, all except one, should there be more than one in a tube, are removed; and the tubes, plants and all, are set in their final destination. The tubes protect the young plants for a time, and, in decaying furnish food for the young plants. By the time that the tubes have completely decayed the plants need no further attention. It is stated that a thousand acres have been successfully and quickly planted in this way, with scarcely

in the shorter perianth tube and filaments about three times as long and not decurved. *J. G. B.*

— Now is the time to test the value of SALUS, for the real, unmistakable POTATO DISEASE is amongst us, and may be rife throughout all Potato crops ere this. We have seen the black blotch with its white mould on the underside of the leaf amidst that earliest of all its victims—the white Regents—at Chiswick, and in several other places, the recent cold rains aiding its development, and inducing it to spread with rapidity. The premature decay found in the haulm of some plants, and especially in the American Rose varieties, although hitherto ascribed to an early development of the disease in some quarters, is now being regarded by growers as resulting from

this stands out specially noticeable as a very beautiful variety. It is one of the specialities sent by that enterprising firm, Messrs. VILMORIN & Co., of Paris, who term it *Iberis coronata hybrida nana rosea*, but it will be better appreciated by the public if simply described as a dwarf rose-coloured Candytuft.

— A few months ago we reproduced some remarks from the *Bulletin* of the French Acclimatisation Society respecting the RAVAGES COMMITTED BY SPARROWS IN ALGERIA, where, it appears, they are excessively numerous. Nevertheless, it is illegal to destroy them, and they go on increasing at an alarming rate. In a recent number of the publication already named there is another letter on this subject, urging the necessity of authorising and even en-

FIG. 23.—THE COLORADO POTATO BEETLE (NAT. SIZE).

the failure of a plant. This method is practised on a large scale for raising the various species of Gum trees especially, but also for raising Pines, Oaks, Elms, Poplars, Willows, &c.

— At one of the recent meetings of the Horticultural Society of France, it was stated by M. COURCIER that the application of nitre or saltpetre to the MUSHROOM BEDS was productive of the growth of very large Mushrooms, measuring as much as 8 inches across the cap. The flavour is described as excellent. No doubt the abundant supply of nitrogen in a soluble form is very advantageous to fungi.

— Colonel CLARKE'S HYBRID PANCRATIOID AMARYLLID is now in full flower in the T-house in Kew Gardens. It shows very little of the *Elisena* strain, differing only from ordinary *Ismene calathina*

the severe check given to the young and tender shoots always found on early-sprouted sets by the cold soil, frosts and rains of spring. It should not be overlooked that this premature decay is nothing new, but has always been found more or less amongst Potato plants after cold springs.

— The seed and florist business carried on by Messrs. BROOK & GALLOP at Brighton, will in future be conducted by Mr. GALLOP, who has lately purchased Mr. BROOK'S interest in the concern.

— Among specialities in annuals one of the most charming and certainly novel is a NEW CANDYTUFT now in bloom at Chiswick. It has a close, neat, compact habit of growth, very erect, and producing large flat trusses of fine flowers of a distinct rosy salmon colour. Amidst a number of the same family

couraging the destruction of these voracious and prolific birds. Wherever there are woods or plantations of trees there the sparrows assemble in incredible numbers. One writer goes so far as to deplore the introduction of Gum trees, because they harbour the sparrows, and it is difficult to dislodge their nests from these slender lofty trees. Now, it is stated that on one estate alone 200 acres of Rye were so completely devoured by the sparrows before it was ripe that not a single corn was harvested; and it was calculated that in a neighbouring wood, some 150 acres in extent, there were 284,000 nests. One colonist complained that the sparrows had carried away 2 tons of his hay; and from the average weight of the nests weighed it was estimated that 10 tons of hay were carried away to construct these 284,000 nests. Further, it is asserted that this same wood, which consists mainly of the Aleppo Pine, is annually infested with cater-

pillars to such an extent that it is dangerous to go through it in the months of March and April, because the Pine caterpillar is venomous.

— It is stated by M. ZOLLER, in a communication to the Austrian Academy of Sciences, that the COMPOSITION OF FUNGI is greatly modified by the duration of their growth, the proportion of carbon in them becoming greater, and that of the nitrogen less, with age, as shown below:—

	Carbon.	Hydrogen.	Nitrogen.
12 day's growth ..	16.11	24.26	38.07
24	5.91	4.83	6.63
31	2.40	3.35	0.4

— *Dulce est desipere in loco* is a maxim to which all assent. The only difference of opinion that is likely to occur is as regards the "*loco*." Our friends in Canada, "The Fruit Growers' Association of Ontario," appear to interpret it somewhat liberally. We see that they relieve their more serious discussions by passing from "gay to grave, from lively to severe." In their annual report for 1876, lately received, we read that at their winter meeting, held on February 16, 1876—

"Mr. DEMPSEY said that he had found in his experiments on hybridisation that the female parent gave the constitution to the offspring. He was experimenting with Apples and Pears, to see if he could effect a union by hybridisation of these fruits.

"Mr. J. MCGILL propounded to the meeting the following conundrum on the subject:—

"Why is Mr. DEMPSEY not likely to succeed in producing good fruit from the union of Apple with Pear?"

"Answer.—In the garden of Eden it was shown to be impossible. The Apple turned the first Pear (pair) out of Eden."

— Mr. SMITH, late of Calderstone, Liverpool, is appointed gardener to Sir F. H. GOLDSMID, Bart., M.P., Rendcombe Park, Cirencester, Gloucestershire. Mr. SMITH is well known as a successful fruit grower and exhibitor at the Liverpool and Manchester shows.

— It is worthy of record that the splendid new ESCHSCHOLTZIA MANDARIN, exhibited at a recent meeting of the Royal Horticultural Society by Messrs. JAMES CARTER, DUNNETT & BEALE, Holborn, W.C., and awarded a First-class Certificate, was derived from *Eschscholtzia rosea*, and not from *E. crocea* as many might have supposed. It originated at the St. Osyth seed grounds, and the well-informed foreman there, Mr. ROBERT GARDENER, having detected on the exterior of the blossoms of a plant of *E. rosea* a tendency to come orange instead of merely rose, duly marked it in order to perpetuate this departure from the usual type. *E. rosea* is of Continental origin, of a delicate flesh-coloured exterior, and a pale rose reverse to the petals. The rosy character is most displayed when the flowers are almost wholly closed. In the case of the selected sport the rose colour had deepened to a reddish orange, and a few years of careful selection brought it to the form of the gorgeous Mandarin. While the colour without was intensifying to the splendid hue hitherto unknown in *Eschscholtzias*, a marked change was going on in the interior of the flower also; the glowing rosy tint gradually brightened into the golden radiance of *E. crocea*. A large mass of Mandarin, now in perfect bloom at St. Osyth, is indeed a fine sight, and it requires to be seen in the morning, or late in the afternoon, when the large showy blossoms are half expanded, to appreciate its superb floral expression. It is then of a rich blood-orange hue. It may be further remarked that in selecting the orange types the rose-coloured form has been considerably improved also. While the work of fixing the character of the Mandarin was in course of prosecution one or two rose-coloured forms appeared, showing not only a greater depth of rose, but with this colour more fully distributed over the exterior of the flowers. The latest selections show this colour to be almost wholly suffusing the exterior, and there is reason to hope it will be presently carried up over the upper portion of the petals and down into the pale-tinted fleshy interior. Then we shall have a truly rose-coloured *Eschscholtzia*. Already a very fine double white variety has put in appearance at St. Osyth. It is as white as the falling snow, and as fully double as an *Eschscholtzia* can well be, unless it is destined to rival the double Tulip in its compound character. It will be heard of by-and-bye, at present it is only permitted to gladden

the eyes of a favoured few. And so, day by day, the commoner flowers are seen putting on new garbs of undreamed of beauty. So illimitable appear to be the manifestations of natural loveliness.

— We have received a liberal schedule of prizes, amounting to about £350, to be competed for at an exhibition of fruits, vegetables, and cut flowers, to be held at the Alexandra Palace on September 13, 14, and 15. Entries close on September 6, and all communications with reference to the show should be sent to Mr. JOHN A. MCKENZIE, 1 and 2, Great Winchester Street Buildings, E.C.

— THE OLIVE is now grown in FRANCE over 147,626 hectares of land, the average produce yearly being 5,500,000 hectolitres of fruit, the yield being thirty-one hectolitres per hectare. According to the official statistics for 1871, it was grown in twelve departments to the extent stated below:—

Var and Alpes Maritimes	Hectares.
Vaucluse	74,363
Bouches du Rhone	27,322
Gard	12,000
Aude	6,115
Hérault	2,416
Corsica	2,000
Basses-Alpes	1,500
Pyrénées Orientales	1,350
Provence	1,200
Drôme	600
Ardèche	277
	129,143

The average produce per hectare was 18.60 hectolitres of Olives. The total produce 2,402,610 hectolitres of fruit, at an average price of 17.84 fr. per hectolitre—the total value being 42,872,550 fr. The yield from the hectolitre of Olives is 13 kilos. of oil and 4.31 of *ressences* or second produce. The total yield of oil is officially estimated at 31,244,025 kilog. of oil, and 10,358,184 kilos. of *ressence*, worth together 44,422,014 fr. Deducting the Olives used fresh, the produce of Olive oil is stated at 26,000,000 kilos., worth with the *ressence* or secondary oil product about 37,000,000 fr. The aggregate value of the Olive in France may therefore be taken to be as follows:—

Value of the oil	37,000,000 francs.
Salaries paid to workmen in the manufacture	2,500,000 "
Salaries to those engaged in the production and sale	1,200,000 "
Value of the <i>marc</i> or cake	2,500,000 "
Olives locally used	7,000,000 "
	50,200,000 "

or over £2,000,000 sterling. This does not take into account the preserved Olives or pick Olives sent into commerce from St. Chamas, Nimes and Gignac yearly to the value of 1,000,000 fr., and the prunings and other parts of the wood. P. L. S.

— We learn that the TESTIMONIAL to Mr. F. W. WILSON, late superintendent of the Natural History Department at the Crystal Palace, will be presented to that gentleman at a dinner to be held at the Crystal Palace on Saturday next. Tickets for the dinner and all further information may be had of Mr. C. E. ELLIOTT, Ceramic Court, Crystal Palace, S.E.

BROWALLIAS.

FOR affording choice, neat sprays for bouquets during the winter and early spring months, or growing as pot plants to furnish warm greenhouses or sitting-room windows, *Browallias* stand unrivalled, affording as they do a great profusion of the most elegant pale blue flowers that are borne in constant succession for a considerable length of time if they are accorded a suitable temperature. The largest and most showy for pot culture is a new species recently introduced, and named after its discoverer, Roetz, the flowers of which are of a delicate azure-blue, and double the size of the old *B. elata* or those of any other known kind. The latter, however, is the best for mixing in bouquets, on account of its extreme lightness, and if used with *Eucharis*, *Gardenias*, or anything of that kind, the effect is most charming, almost equalling that produced by the lovely *Myosotis dissitiflora*, which is always a favourite for that kind of work, as, independent of the sentiment attached to it, there is a likewise a delicacy of colour and such grace and beauty of form that it never appears out of place. Unfortunately the *Myosotis* can only be had in spring and early summer, while the *Browallias* may be enjoyed during the whole year, and appear at their

best during winter if sown in time and properly managed.

Used as we had it here at that season, slightly elevated above the heads of *Eupatorium* *Weismannianum*, white *Chrysanthemums*, *Spiræas*, &c., the effect was most pleasing, and it was at the same time in great request for cutting to use in vases, where I was glad to find it surpassed in lasting properties many other things of far greater substance, as at the end of a week they looked just as fresh as when severed from the plant. This enduring character is no doubt owing to the nature of the stems, which are somewhat soft, and take up water freely, and appear as if they would emit roots if the light and other conditions were favourable.

There is generally a difficulty during winter in getting a change of plants suitable for table decoration; but with a few *Browallias* in 6-inch pots to fall back on nothing better can be desired, for except under artificial light there is no colour that shows up in more pleasing contrast with a white cloth and the other etceteras than a pretty shade of blue like that of the *Browallias*. Those who would have them strong and in bloom by Christmas and after should obtain seed and sow at once in pans or pots of light rich sandy soil, and place the same in any close frame or handlight where they can be shaded till germination takes place. As soon as they are large enough to handle they may either be pricked out to gain increased size, or at once potted three in a pot or singly, according to the specimens required. In the former way they form fine masses for conservatory or greenhouse decoration or to cut from, and in the latter they are the most suitable for window recesses or any purposes of that kind.

After the potting they should be stood in a pit or frame and kept syringed every morning and evening, to ward off the attacks of red-spider, to which they are very subject if a dry atmosphere be allowed to prevail or the plants at any time suffer from want of water at the roots. *Browallias* delight in a rich open soil and plenty of liquid manure after they begin to show bloom, and this should be administered freely, but in a properly dilute form, and such as is made from sheep or cow dung and a little soot in preference to any other, as that is always of a cooler nature and more suitable and less risky than what is obtained from any of the artificial compounds. To keep them dwarf and bushy it will be necessary to stop them two or three times during the remainder of the summer and autumn, and as they will not stand cold they should be housed by the end of September, or their leaves will begin to fall off.

A temperature ranging from 50° to 60° suits them best, as in that they continue to grow and flower in the freest manner possible, but if the atmosphere be dry and they are stood away from currents of air they will endure a few degrees lower without suffering any injury. If by chance this should happen they may soon be got round by placing them in a cool stove, which is the best situation for them when required for cutting, provided they are kept well up to the light, so as to get the flowers properly coloured and of good substance. By sowing again at the end of August or a little later on, a good supply of bloom may be had till quite the end of May, especially if the seed-pods are picked off as they form, as these tend more to the exhaustion of the plants than double the quantity of flowers would do. J. S.

CONFESSIONS.

WE read in Holy Writ of the prodigal son confessing to his father that he was "no more worthy to be called his son." Augustine of the olden time, who to great learning added candour and humility, wrote his celebrated confessions, thereby rendering great service to society. David erred, but his repentance has been the pattern of a true penitent for all time—

"He is not free to keep the road who is not free to stray."

But we have in our own day, and apart from Holy Writ, the confession of a scientific author, who was so drugged with opium that his life was a hell upon earth, and he has in glowing terms given us his confession. Talk of "Blue Devils," he had them of all hues; they frothed up from the water, crawling and slimy, and they fell from above, disgusting monsters of enormous size. These confessions having gone the round of the papers will surely warn the unwary against the horrors of this deceitful drug, and those of its near ally, the abuse of ardent spirits. Now, I

believe that if the misery that is quite within the power of man to alleviate, were only confessed and known, were only once well told by a trustworthy narrator, "our tears of pity could not be suppressed." In the city of Manchester, where I now sit, there are hundreds of excellent carpenters hanging on all day about their rooms waiting for "the rare time coming, boys," of 9½. an hour, but

"The strokes yet echo of contending powers,
Want thunders at the door and curses idle hours."

The labourer who cultivates the soil sees all this, and hardly believes that there is such a charmed life to be led in this world of woe: he prays "Oh, that for me such luck as half the 9½. would arise." The case of the agricultural labourer has been taken up by able hands. One of the staff of a London contemporary herded with Hodge for a time, and gave, in glowing terms, the true state of matters in that cabio, showing beyond all question that "hard is the fate of the infirm and poor." My business is not, however, with the agricultural labourer, but with the wages of young gardeners, and labourers who, from long experience and good behaviour, are more or less skilled in horticulture. The rate of wages in the London nurseries in 1832, when I bought my information in that quarter, was 12s.; it was the same in the Royal Gardens at Kew and elsewhere, and at Kenwood, the residence of the Earl of Mansfield, it was the same, with 6d. a day added to each of the two foremen. The bricklayer's labourer gets 18s. a week, for his "superior" sees that his satellite's interest is attended to, he himself having been rewarded with the 9½. for some time. The carpenters and bricklayers have their clubs and their organisation, and the farm labourers have an apostle in the person of Mr. Arch to look after their fortunes, but the proportion of garden workmen to agricultural workmen would be only about one in 100. They are, therefore, not the bundle of rods bound together by strong ties of any kind, but rather the single twigs that an opponent of any kind might easily bend or break. I, the writer of this, did the honours of gardener in chief for a titled family for £60 a year. This was settled before leaving London, but the board wage was not, and I was allowed 9s. a week. It was my first situation, and I confess that I bowed my pride rather than my prospects. Dr. Lindley asked a friend of mine who was similarly situated, "Why did not you leave, and let him serve himself?"

It may not be out of place here to name some items of London life enjoyed by young Scotchmen when they turn their faces southward. The miserable lodgings—for want of means—makes home a nickname. The life in some of the Scotch bothies, where they are well ordered, has many redeeming qualities, and the peace and retirement for reading and study are worth a good deal; whereas the noise and bustle of a cheap lodging-house bars that kind of progress, for poverty pervades every part. As an example to the point, I was asked by a Scotch farmer to let him know the prices of beef, butter, eggs, &c.; I told him what I saw on every butcher's stall marked, but I confess that I could not tell the price of butter, simply because I had not bought any for a year or more. Little did my kind mother think that I was living on little better than bread and water, using a 2 lb. loaf daily. Mutton broth was a standing dish, the dietary being three meals, supper not being indulged in for weighty reasons, for in the London nurseries the beggarly pittance of even 12s. a week could not be relied on, since foul weather would occasionally lessen that sum, or stop it altogether—for who has not heard of the London frozen-out gardeners—and, although I never saw the Cabbage on the pole during the seven years that I lived in and near London, I can easily guess how the drunken idlers would raise the wind in that way. Many of the London labourers had come to work in gardens as a last resort, as they needed no recommendation from their last service. We had a dancing mister on our staff, delving for the bare life; and when his relations got him an invitation to do the light fantastic toe he had to do his own washing and clear starching—for he was a single gentleman—and had to hail a cab to carry him across the street to the club house for 6d., it being imperative to come in state, and to do this on 12s. required some scheming. What a blessing paper collars would have been to our James H—in those days! Moreover, his confession of being a dock labourer, where they stood like slaves to be hired, and were searched like thieves on

leaving, showed that bad as work in the nurseries was, it was better than the dock work.

Young men from Scotland and Ireland, accustomed to garden work, and in some cases regularly apprenticed to it, seeing the small chance that they had of bettering their condition in the gardening way, got better wages as letter carriers, and so took to the livery for a livelihood, and left their first attachment. One promising young gardener, who had lived under several masters, had landed in the nursery to wait for hiring, and led a charmed life; being an excellent fiddler, and having some abilities as a poet, he had spent a good deal of valuable time amusing others but not benefiting himself, and had to take to the police force for employment, and when the writer saw him last he described his service as "crawling like a toad on a ruin."

I must give one more illustration of life in the London nurseries. Our subject was by trade a hairdresser, with what is called in gardeners' advertisements "encumbrances," for he had three unchristened children, besides an infant just born. The mother was anxious to get her family baptised, but they had no clothes to appear decently in, for the furniture had been pawned to buy bread. I have never forgotten the supper of that family, for each child got a halfpenny cake and was sent to bed, but I did not see anything forthcoming for either the husband or the wife. The wife eked out the husband's 12s. by taking in two lodgers, of whom the writer was one, and now relates what he saw. We got the hairdresser into the Metropolitan police, where, besides his wages, he got business as barber in the force, and from that time he was a made man. I mean to show that the mere labourer in those days had a miserable time, and was glad to turn a mangle in his spare hours, or carry a sedan chair for some elderly lady who still preferred that ancient mode of travel.

In order to give young men some idea of what they may expect to find in London, I may remark that wages have risen a little during the last forty years, but some of the necessities of life have risen also. The Scottish schools once gave young men from that country an advantage which they do not now enjoy. On this head I may as well state that the young man who has not been well educated, or has not had a good moral training, had better stay at home than compete with the southern natives on their own soil. No one can make much way with botanical names who has not been well grounded in Latin, but there is another qualification which must be kept in view, and that is to keep some hard cash always in hand. I might confess how useful I have found this article, and what pains it has cost me to board it against sickness, which, thank God, I have never suffered. I may as well confess that the "rust" of ardent spirits, and the "moth" of tobacco, have never eaten into my purse. The man of fortune may use these, or even abuse them, with comparative impunity; but the number of gardeners that have died rich out of all my acquaintance I could count on my fingers. Still, there is a fair field for good men, for the late Dr. Lindley said if he wanted a trustworthy man, well up in horticulture, he hardly knew where to find one.

A thrifty Scot of my acquaintance, with praise-worthy forethought, bought some oatmeal, with the idea that with living as in Aberdeenshire, his 12s. would do wonders; the landlady of the lodging-house cooked the brose according to his instructions, but it could not be used as food. Ridicule is a great power, for when you are in Rome you must do as Rome does, and it may save others some trouble to know that this experiment has been tried. There is a limit to saving and low living, for I could point to two powerful men in the prime of life who sacrificed too much; one died a lingering death, and the other from nervous debility lost his sight, and when too late both confessed that they had starved themselves.

Let no young gardener deceive himself in his business, it is not to be learnt at a cheap rate, and when it is attained the remuneration in good places is but very moderate. Our only means of improving our condition is by good conduct, which every generous employer will see and appreciate when the matter is honestly set forth. It is quite a marvel how the writer has lived through all the long years of suffering, low wages, early and late hours, and hopelessness as to bettering his condition, which have marked his gardening career—

"Happy whom none of these befall,
But this old gardener knew them all."

A. F.

ANATOMY AND FUNCTIONS OF THE LEAVES OF *DIONÆA* *MUSCIPULA*.

We have already noticed Mr. Casimir De Candolle's paper on the anatomy, &c., of Venus' Fly-trap (*Dionæa muscipula*). The following, which agrees with it in the main points, is a summary of a more exhaustive article on the same subject, by Dr. Franstadt, which appeared in Cohn's *Beiträge (Zweiter Band, erstes Heft, pp. 27 to 64, plates 1 to 3)*. The most important fact established by both observers is the nature of the bristles or excitable hairs on the face of the blade of the leaf; these differ from the epidermal productions (glands and stellate hairs) in having their seat in the fundamental tissue of the leaf, and from the marginal bristles in having no vascular bundle. Dr. Franstadt appears to have had only very small plants for his experiments, and he expresses a doubt concerning the much larger dimensions recorded by other writers, but we are able to verify them up to the largest size he mentions.

Each half of the blade of the leaf is somewhat S-shaped, forming a hollow for any animal that is trapped; the broadly winged petiole is flat. The cells of the epidermis, as well as those of the fundamental tissue, are elongated in the petiole and midrib in the longitudinal direction of the leaf, whilst in the two valves of the blade they are lengthened at right angles to the midrib. The cells of the epidermis also contain chlorophyll. They produce numerous stomates on the upper and lower surfaces of the petiole, and on the lower surfaces of the blade; but on the upper surface of the blade, glands only. The glands stand in depressions of the epidermis, and are formed of a two-celled basal portion, a two-celled short stalk, and the convex glandular body itself, which consists of two layers of cells. The stellate hairs are of analogous structure, save that the upper layer of cells grow out into long radiating tubes. The stellate hairs appear much earlier than the glands, being fully formed before the latter are begun. The toothed blade bears a number of prickles on its upper surface, usually six. The teeth or marginal bristles are slender three-sided pyramids, but with stellate hairs and stomates on all sides, and containing one vascular bundle nearer the upper than the lower surface of the leaf. A stellate hair is seated in each of the bags formed by the marginal bristles, sometimes on the summit of a blunt pyramidal elevation, which however contains no vascular bundle—the prickles or central bristles, of which there are usually three on each half of the blade, arranged in a triangular manner, the apex of the triangle next the midrib. They consist of two parts; the basal portion acts as a joint or hinge, and contains an axile strand of cells; the upper cone-shaped portion is constricted at the base, and wants the axile strand of narrow cells. The cells of the central bristles, as well as those of the glands, have a tendency to aggregation. In the above-ground green parts of the petiole, and in the midrib, the cell cavities of the fundamental tissue increase in size, both in length and breadth, from without inwards. The more superficial cells and those contiguous to the vascular bundles are green, the other (inner ones) are colourless. The cells of the blade of the leaf, with the exception of the midrib, form a sponge-like tissue of very large colourless cells with wavy walls, and a few small intercellular spaces. The cells of the epidermis of the upper surface of the leaf, as well as the cells of the fundamental tissue underlying them, are larger than those of the under surface. The grains of chlorophyll contain abundance of starch granules before the leaf has absorbed any animal food. The starch decreases with the absorption of substances through the leaves, and finally disappears completely from the parts above-ground. The basal portion of the petiole is expanded, forming together a kind of bulb. Their fundamental tissue contains only cells of uniform length and breadth, which are completely and exclusively filled with starch both before and after the absorption of organic substances. The starch granules in the blade and the part of the petiole above-ground are oval, whilst those in the underground sheathing part of the petiole are cylindrical. The living cells of the leaf contain a colourless substance in solution in the cell, which is precipitated by bases in the form of dark-coloured granules, and again dissolved by acids. The glands contain no starch. The red colouring matter of the glands is changed green

by strong bases, and reproduced by acids. Colourless glands were reddened after absorption of albumen and dyed red, as well as the vascular bundles, even in the petiole, which constitutes the actual proof of absorption. In decaying black granules are formed in the tissue of the leaf, which produce black spots on the leaf. In the midrib of the petiole is a very thick axial vascular bundle branching off into the wing in curves, each branch forking again and again in successively thinner branchlets, but without symmetry. The midrib of the leaf is only traversed by the large axial vascular bundle, which branches to the right and left at right angles, each branch forking near the margin of the blade and uniting again, and running into the marginal bristles. The phloem of the vascular bundle consists of soft bast, the xylem in those of the blade exclusively of spiral vessels, associated with other vessels in the petiole. In the young state the blade and petiole of the leaf are undistinguishable, and the blade is much behind the petiole in its development. In the young state the valves of the blade are rolled inwards. The stem is short and thick, with a ring of wood, and obliquely pierced by vascular bundles, one entering each leaf and each root. The secondary roots are long and strong, and never branched. The cells of the tip of the root are coloured red, and the bark cells in a centripetal direction brown, dying off up to the sheaths of the vascular; the vessels arise in the periphery of the axial vascular bundle, increase in a centripetal direction, and form an eight-rayed star.

QUEEN MARY'S BOX BOWER.

MARY QUEEN OF SCOTS was a constrained inmate of several gardening places in an age when gardening was as yet but rudely practised. A garden of her later years may still be seen at Chatsworth, an unattractive raised platform, moated and walled round, where she was permitted, as a prisoner, to walk without her guard. Some rather touching verses are inscribed on the flight of steps by which the unhappy queen ascended to her promenade. They are as follows:—

"The moated bower is wild and drear,
And sad the dark Yew's shade;
The flowers which bloom in silence here
In silence also fade.
The Woodbine and the light wild Rose
Float o'er the broken wall;
And here the mournful Nightshade bows
To note the garden's fall.
Where once a princess wept her woes
The bird of night complains;
And sighing trees the tale disclose
They learnt from Mary's woes."—A. H.

There could not be a more fitting memorial than a garden of one who stirred so many hearts when living and still moves them in memory. And in Mary Stuart's own country we find another fit memorial of her on one of the islets on the Lake of Menteith.

After the battle of Pinkie in 1547, Mary, a mere child, was removed for safety to the Priory of Inchmahone, and here for a few months she remained attended by those four other Marys, her maids of honour and playmates, whose names are so familiar to all who have read the story of her life, especially as written by Sir Walter Scott.

Landing now on this lovely islet, where the little playful Mary cared as little for the English invasion as a goldfinch in its cage, the beautiful ruins of the Priory are close at hand, half buried among trees. You approach and admire the graceful arches of the ruined nave, the deeply recessed entrance and its exquisite mouldings, the tomb of the Earls of Menteith and the groups of tufted Chestnuts which nobly typify the earls whose dust has sustained their growth. The trees are of great size, measuring 16 feet in the circumference of the trunks. A small rookery now holds noisy possession of these trees, and lords it over the roofless church. You find the rooks holding council here, sole inhabitants in succession to the monks, and on your near approach they tamely fly to other trees on the island which, at the widest part, is but a stone's-throw over. A few steps brings you to Mary's Bower on the opposite coast. In the guide-books generally nine Box trees are noticed as remaining of those which formerly composed the Bower, and we read in Dr. John Brown's *Hore Sub-*

sevia of 1861—the second series and not the best—"there are the remains of a double row of Boxwood all round, the plants of Box being about 14 feet high, and 8 or 9 inches in diameter, healthy, but plainly of great age."

That seems to have been the state of the Box Bower in 1861, at present we only find one poor straggler remaining of the original plants, a naked pole with a single bunch of leaves at the top. The Bower in which the Marys played—Mary Stuart, Mary Bethune, Mary Fleming, Mary Livingston, and Mary Seton—now consists of an outer hedge of Box, young, green, and healthy, and enclosing the space which the older trees roofed in. And where are the descendants of the Marys? They left the Priory when Mary Stuart was six years old, to embark at Dumbarton, on the Clyde, for France, and to acquire polite accomplishments and poisoned manners. And to this day fashion and poison are occasionally administered in one dose, as in the sixteenth century. E.

Home Correspondence.

Roses at Cheshunt.—The old adage of "all is not lost that is in danger" has, in the matter of Roses this year, been verified. The unseasonably mild winter started them into growth sooner than is their wont, and the subsequent scathing eastern winds and nipping frosts, that continued almost without intermission through April and the beginning of May, caused gloomy forebodings amongst growers that Roses would be a complete failure; yet such has by no means been the case, for although the general bloom has not this season been equal to that of some past years, still some of the leading growers have shown them very fine. Cheshunt has held the most prominent position at most of the leading exhibitions, such as the Alexandra Park and St. James' Hall, at both of which Messrs. Paul & Son were 1st in the large classes of seventy-two as well as forty-eight varieties, in addition to holding a similar position in many of the smaller classes. About the middle of July I took a run over to Cheshunt to see the newer kinds growing, for seeing a Rose on the exhibition stage does not tell all about it to the full extent as when seen in quantity on the plant. Of last year's new Roses that have here proved well, and which I saw in fine condition, especially may be named Mrs. Baker, much brighter than Victor Verdier, from which it was raised; a strong grower. Miss Hassard has fully realised all that was expected of it. Madame Prosper Langier really fine; Avocat Duvier, fine; Abel Carrière, a grand dark rose, which may be described as a large Prince Camille de Rohan; Duchesse de Valombrosa—imagine an almost white Jules Margottin, and then its character will be understood; Marguerite Brassac, a more vigorous growing, lighter coloured Charles Lefebvre. Duke of Connaught was in splendid condition—a Rose for everyone who grows Roses. Sultan of Zanzibar, another of what may be termed real garden Roses to prolong the season of blooming profusely right through the autumn, at the time of my visit was not fully in flower. Of this year's new English Roses, Emily Laxton and Marchioness of Exeter both promise well. Of the new Roses for next year Robert Marnock may be described as a rich brownish crimson, very distinct in colour and very fine; Mrs. Laxton, a light crimson, intermediate in colour betwixt Marie Baumann and Sénateur Vaisse—a finely formed flower; Climbing Bessie Johnson, identical in colour with Bessie Johnson, from which it is a sport, with a decided climbing habit; John Bright—this Rose improved very much as the season advanced, it is a rich, glowing, very dark, bold, imbricated flower. Totally apart from what it may turn out to be as an exhibition variety, it is unmistakably one of the very finest garden Roses ever raised; in the whole of the Roses here, comprising many acres and every proved kind worth growing, I saw nothing amongst dark kinds equal to it for general effect. It cannot fail to become a universal favourite. T. Baines.

Lilium cordifolium.—Of course I do not wish to contradict the statement of so experienced a cultivator of Lilies as Mr. Krelage, but besides the change in constitution in *Lilium cordifolium* it appears to me that much of the apparent change is due to natural variation. I very well remember the large bulbs of the *L. cordifolium* introduced by Mr. Fortune to the Sunningdale Nursery, now twenty-four years ago, which were of a much stronger strain than any cordifolium I have since met with, but I am of opinion that those which we now cultivate are derived from a race naturally inferior to those I saw twenty-four years ago, and that their flowering earlier is not so much attributable to accommodation as to natural inferiority. I have plants of *gigantum* which horticulturally are very distinct from each other, at least as regards development of leafage and

in general outline, and I am convinced that some of them will be larger in any way than others. *L. giganteum* grows in its natural habitat even with the surface of soil; *L. cordifolium* is sometimes found 1 foot deep, imbedded in the soil of forests of Japan. Max Leichtlin, Baden-Baden.

Tuberous-rooted Begonias.—The garden here has lately had many visitors, some of them having good gardens—a few having great gardens—of their own. All fasten on the bulbous Begonias planted out in the rootwork, and express great admiration of them. It therefore seems that though these Begonias have often been recommended for planting out, the use of them for this purpose is yet but little known. Here we have four beds, principally of seedlings, of *B. Sedeni*. These are beautiful in colour, and constantly improve in effect as they grow up; but the flowers do not show up as well as in the rootwork, and, being in a more exposed place, are more damaged and splashed by wind and rain. The dark old roots, and the green of the dwarf shrubs, too, make a telling background for the rich scarlet. Among our most effective are Veitch's *Vesuvius*, Lemoine's *Corail Rose*, and Wm. Leibrecht—these two last showing the blood of Veitchii. *Sedeni*, *Corsair* and *Maritana* are also very handsome. The colour of *Froebelii*, beautiful as it is, is less rich than in a plant in the greenhouse; perhaps it had a check. Near them is a rather happy combination of two Lilies—*L. testaceum* and *L. Martagon dalmaticum*, whose heads nod together, the buff of the first harmonising well with the rich purple of the second. A *propolis* of this last, when at the last South Kensington show, speaking to some Lily growers of the strength it had shown with us, being 5 feet 8 inches high, with twenty flowers to a stem, this was considered a very great success; but on Saturday Mr. Ellacombe, of Bitton, who was here, told me that he has a plant much finer—taller, and with twenty-five blooms to a stem. *George F. Wilson, Weybridge.*

Crocuses.—I can substantiate the remark of a correspondent of *Nature*, noticed at p. 82, that sparrows eat yellow Crocuses in preference to those of other colours, but I cannot make out clearly the reason. The first year that I had many thousands planted in a town square they never seemed to touch them, but the second year, and many years after, as the signs of the golden flowers appeared, they cut them off as if they had been clipped with scissors, the birds running along the ground by dozens and seizing the flowers on their first peeping forth. *F. F. Johnson, Belfast.* [The fact is notorious. Eds.]

Ginger Injured by Insects.—With this I send you a sample of East India ginger. Please say what the two devouring elements are. You will find the small Coleopterous borer in all stages of development amongst the *débris*. It is well known in the trade as the ginger beetle, and its ravages are recognised by an average percentage, from which there is not often any serious departure. But what is the beast that has been doing the greater damage by shelling the rhizomes? The gentleman who brought it to me has been growing, curing, packing, and shipping ginger for nearly twenty years, and he never saw the like of this before. I suggest *Blatta*. He says that he never knew cockroaches guilty of such a thing. Has the famine reduced them to such straits? But this damage must have been done on board ship, as the landing weight is so much less than the shipping weight of the parcel. I should like to know the proper name of the beetle; and my friend would like to know the name of the creature that has cleaned out the inside of his ginger. *W. T. T.* [I do not think there are two "devouring elements" here. I imagine that the small borer has done the whole mischief, and my reason is that I have seen the same thing in the food collection of the South Kensington Museum, where the little borer is a great trouble to the attendants. When it has only bored a little, the borings seem trifling, but as it goes on the whole interior is reduced to powder, and nothing but the skin is left. The name of the borer is *Nyctelius pectinicornis*. As to cure, I should say alter a letter and make it *care* in packing, in clean boxes not filled in infected storehouses. *A. M.*]

Fruit Gossip.—To-day (July 18) we had an excellent dish of cooked Pears, consisting of those of 1876 and of those of 1877. I merely mention this as "gossip," but, with others, I think this kind of detail is often instructive, or, at least, suggestive. At any rate, after long experience, I never did this before without any trouble whatever. It is an abnormal fruit season, there is now no doubt of it; generally bad, however. Indeed, here, out of the six varieties of my own mildew suddenly appeared in one—a rather out-of-the-way structure, sixty years old, and so uncared for—and thence it reached an adjacent vinery, the "villa vinery" of my own invention, and which is thought well of by many, which is quite new. In the first it soon became general, even to the leaves; in the second case only a few isolated berries

showed signs of Vine mildew, evidently carried to it by the wind. So we cut these out at once; but, in the case of the old viney, after sulphuring once or twice, we proceeded to take soft cloths, and, wetting them slightly, to powder them with sulphur, and then softly wipe away the net-like poison, which would have prevented the berries from swelling; already, after a second wiping, the berries look better. It is true that the bloom is gone, but experience has before this shown us that berries wiped even six or eight times are saleable, and not much smaller in size than usual. Indeed, I have no faith in sulphur as an absorbent of mildew. In itself it is worse than a wiped berry, and must be syringed off carefully, thus removing the bloom. I only use it as a material which, like emery powder, aids to "polish" the berries clean. It is sad to think of those who will eventually consume these Grapes thus "polished," but it is the only way I know. Personally I should object to eat them, although their appearance is not at all irregular, nor worse than the average look of Grapes cut by careless and dirty men, and thrown, like common vineyard Grapes, into a basket, as is often done. In other respects the orchard-house fruit is very good here, and large, but then I employed in the spring a discharged prisoner (being a prison chaplain myself)—a strong fellow—and made him deluge the borders for weeks. Since then, my servants have, as usual, cut off this supply, but they have been unable to undo the excellent effects of my "discharged" friend's efforts. If any amateurs, then, desire fine Peaches, let them employ similar means. Three hours a day at the pump during the growing season is a healthy and fruit producing process. We never had finer Peaches: others complain of small fruit, and even of hardly any. *Thos. C. Bréhaud.*

Garden Design.—I wish to draw attention to one particular in your excellent article on "Cliveden" last week that appears questionable. I do this for the advancement of the art of garden design, not to find fault. Much may be forgiven at Cliveden, where so much has been successfully accomplished; for to attempt great works in art great comprehension is required to bring the resulting effect into its proper time and place. Thus the failing effort of great attempts is often superior to the success of puny desires, as the aim at greatness shows the road to excellence, whereas puny efforts breed but contempt. It is the account of the flower garden at Cliveden in your last issue that is likely to do harm (particularly to young students) by the character of excellence attributed to it above "a variety of designs by various landscape gardeners." I have given many years of study to such-like designs without gaining much knowledge from them of the principles of landscape which teach how to produce the charm which high art should impart to cultivated minds. In studying to work out any feature of beauty, harmony seems to be the focus-point on which the many particular powers of effect should converge. Such are the various parts of a design, its outlines, lines of sight, distances, and character, all of which must have their time and place in order to realise the beautiful; but if harmony is necessary to the beautiful in landscape, the design of the flower-garden at Cliveden is greatly wanting, for it is but patchwork, and the lovely landscape surrounding—divinely lovely, if you like—is cut in pieces (when this garden is the foreground to the views) by the lines of the design being false to its surroundings by giving an impression of equality—good, bad, and indifferent, all being of equal importance; it has no point of excellence, but equality instead. I went to see this garden some time ago, and confessed that I could not see its beauties. My conductor replied, "Oh, but you should see the spring flowers!" No doubt the spring flowers of themselves are beautiful, but the design is, in my opinion, "unsuitable" for its object. *Joseph Forsyth Johnson, Belfast.*

¶ **Strawberry Anna de Rothschild.**—This fine late Strawberry deserves to be more generally known. In the neighbourhood of London, grown among the largest collection in the country, it is just beginning to come in, all the others are nearly quite over. It is very large, bright scarlet, sweet, and well-flavoured. *E.*

¶ **Abies Engelmanni.**—I endorse the remarks of Mr. Barron in the number of July 14, as to the question of *Abies Engelmanni*; until now I thought I had the true one, but which of the two now come in controversy is the real *Engelmanni* is a question which must be settled by competent men. I am quite sure that different parties must have different plants under the same name, and only from this point of view can I understand how it is possible that *A. Menziesii* is mixed up in this question. I quite agree with Mr. Barron, and protest with him in bringing *A. Menziesii* on the stage, this species having in fact as little to do with the *A. Engelmanni* as the *A. Nordmanniana* or any other coniferous plant. Follow the advice of Mr. André and let a branch of *A. Menziesii* go through your hand and you will be

severely hurt, whereas *A. Engelmanni* is quite smooth. (This is also quite characteristic between *A. Menziesii* and *A. sitchensis*, the latter showing a great difference in this respect.) My original plant of *Abies Engelmanni* came from Orleans, is splendidly glaucous and quite hardy. I hope this question may soon be settled, that we know what we have. *John Booth, Flossbeck, Hamburg.*

Sports from Gloire de Dijon Rose.—To last week's *Gardeners' Chronicle* you take notice of a pink sport on the *Gloire de Dijon* Rose, and also of the same thing having been observed in Norway. I send you a flower, which I presume is darker than those formerly described [Yes], which has been produced here on a young shoot springing from the old hard wood, 1½ inch in diameter. The plant has been a good number years in its present position, and covers a wall 12 feet by 8 feet, and the sport has pushed out from where the wood has got bare and hard,

FIG. 24.—SPORT ON GLOIRE DE DIJON.

and could not have been budded. The smell is that of a Perpetual instead of a Tea Rose, and quite double, and as far as I can recollect it was worked upon a Brier stock. On the other side I give you a sketch of the position of the sport (fig. 24), showing it to be far removed from the junction of bud and stock. The arrow points to the exact spot where the branch of young wood springs from, no other young wood or leaves being near it. The plant is vigorous, and produces annually large crops of flowers of the largest size. I mean to retain the shoot in order to prove if it will be permanent. Should this be of any interest to you it is at your service. *A. Anderson, Oxenford Castle, July 17.*

Ashantee Hammocks.—Among garden sundries this may advantageously be included. It is a great luxury in a garden, and may be used in or out-of-doors for a great variety of purposes. We once saw a young

FIG. 25.—ASHANTEE HAMMOCKS.

maiden learning her lessons under the greenwood tree in one of these hammocks. Indeed, their handiness is such that we may safely recommend them to those who have not yet tried them. Messrs. Seydell, of Birmingham, are the makers.

The Potato Disease: Harvesting.—After the perusal of Mr. Worthington Smith's very valuable and interesting articles on this disease in the *Gardeners' Chronicle* of July, 1875, it struck me it would be desirable that some growers of the Potato should, in the autumn of the following year, adopt various modes of harvesting that crop, and carefully register the results, and report them in the *Gardeners' Chronicle* prior to the maturity of the crop of 1876. This suggestion, with my intention of acting on it, appeared in the *Gardeners' Chronicle* in August of that year. The details of my treatment of my crop in that season having been reported in the *Gardeners' Chronicle* it is unnecessary to repeat them. I have not seen such report from any other grower. I have deferred my report of my treatment in harvesting my crop of last year until this critical period for action in

reference to the harvesting the crop of the present year. My beds are thrown up in the autumn 12 feet wide, leaving alleys between about 12 inches in width and depth. I never use any manure for this crop. The Potatoes were planted entire, with few exceptions, 2 feet apart in the rows, which are 3 feet apart in March and 5 inches deep, to retard their too early appearance above ground in the spring. At the end of July, 1876, on a careful examination of the crop, I found the haulm and leaves in a green, vigorous state, without the usual indications of disease on either. On inquiry amongst my neighbours I received the same encouraging reports; indeed, such were the reports given in the *Gardeners' Chronicle* in the month of August from Scotland and various English counties. About the middle of August occurred some heavy rains after some very hot sunshine, and the haulm still appearing green I apprehended sprouting of the tubers under ground, and bearing in mind the success of an experiment on a small scale under similar circumstances at a former period of drawing off the haulm by the roots, I resolved on adopting that course throughout my entire crop. The Potatoes were formed in point of size, but as yet unripe, the skin not being set firm. At that date I desired my gardener and his assistants would, placing one foot on each side the plants, carefully draw the haulm by the roots without disturbing the tubers. The last week in September, having found them thoroughly ripe, the Potatoes were forked up on the surface to dry, and were then wheeled for storing. On a casual inspection while lying on the surface the crop appeared free from disease. The men were directed to examine carefully every Potato before it was stored, and to set aside all in any respect unsound for my inspection. A piece of ground was set apart for this purpose, 6 feet wide, and the Potatoes were placed on this in the shape of a cone, carried as high as they would remain, leaving a foot margin of the earth around it. The heap was lightly covered over for a week, preserving a free circulation of air through it. The outer soil was then thrown on the margin left, and over the heap about 8 inches thick, thus leaving a hollow space all round to carry away any drippings from the thatched roof over all. My gardener sent in to me the unsound tubers which were found on storing the crop—four in number only, three of which had clearly been partially eaten, the remaining portion when cut through being quite sound. I enjoyed the notion that I had at last secured a sound crop of this useful esculent, until I was alarmed on reading in the *Gardeners' Chronicle* of October 28 as follows:—"The Potato disease is reported to be very bad in the neighbourhood of Cirencester." On inquiry I found such to be the result on digging crops which had appeared in as safe a state as my own the beginning of August. Soon afterwards I saw a report of a case in which it was stated that on opening a store of Potatoes (whether pitted or otherwise did not appear) quite free from disease apparently when stored a large proportion was found diseased. It was not without some fears that I determined on uncovering my heap and removing the contents into my cellars the last week in December. Being confined within at the time, I desired the men would measure the sound Potatoes sent into the house, having carefully examined the store, and laid aside for my inspection every questionable tuber. The basket brought to me contained nineteen tubers only, making, with those four previously stated, twenty-three faulty tubers out of a crop which filled seventy-two bushels. A large proportion of the nineteen were particularly eaten or bored, the remainder were not examined. This crop more than supplied my family in sound condition to the beginning of this month, when the young Potatoes of the season were ripe for table. Such is a mere statement of facts on the accuracy of which your readers may rely. I may add the variety I have described is Paterson's Victoria, which I obtained from the late Mr. Paterson within a year or two after its introduction, now some fifteen or sixteen years ago. The perfection of this variety in my soil has induced me to rely on it solely up to the present time as my annual crop. I have this day gone very carefully over this year's crop from the last year's seed, and I could not find the brown spot on the leaves or stem of a single plant. *Charles Lawrence, The Querns, Cirencester.*

Early Lettuce constitutes one of the principal crops grown in the Fulham district for the London and large provincial markets, and they are produced in great perfection. The London White Cos is considered the best, as it commands the best prices, and when seen well done may be called a "giant," or "magnum bonum," liberal treatment and a fair allowance of room being the essential points to obtain them large and crisp. The principal crop is sown in frames as near the middle of October as possible. The ground is marked off for the frames, and the soil is thrown out of the intervening spaces, on to the top of these, till they are raised about 18 inches at the back and 1 foot at front, above the level of the surrounding ground. These ridges are nicely levelled over, and the frames arranged on them. They are sown with

the Early Dutch Horn Carrot, the seed is covered with a good sifting of dry soil. The Lettuce is then sown on the top of this, and covered with a sifting of dry soil. "Carrots require deeper sowing than Lettuce." The glass is put on, and a person appointed to attend to the airing and scaring of the sparrows. As soon as well vegetated they are gently thinned to about half an inch apart and the glass taken off on all favourable occasions, and tilted on damp days—keeping them thoroughly dry over the winter, and well protected from severe frost, being the chief points during the winter months. About the end of February or beginning of March, according to the weather, they are planted out on well-prepared ground in rows from 14 to 16 inches apart, and from 9 to 12 inches in the row, according to the intended intervening crops, which are generally spring-sown Cauliflowers, Kidney Beans, Scarlet Runner Beans and Seakale. Kidney Beans are sown between every other row of Lettuce, and Scarlet Runners between every second row; as the Lettuces are cleared off their space is planted with Coleworts or Lettuce. There is no restriction or rotation of crops in market gardening as in farming. As soon as they are large enough they are gone over, and the best tied up; one tie is sufficient, and this is once all the season. It keeps them clean, and saves them from breakage in their transit to distant markets. They are always packed and sent to market as drawn. They keep longer fresh with the roots left on. A second sowing is made the beginning of February on a slight hotbed under glass. As soon as they are well hardened off and large enough they are planted out as above, and come into use in the later part of June and over July. The following sowings are made out-of-doors. Many remark that there is always a good stock of Lettuce and Coleworts for any vacant ground that turns in. The Early Dutch Horn Carrots that were sown with the Lettuce are considered the best for early forcing. When the Lettuce plants are removed they are nicely aboveground, and are thinned to about 2 inches apart and receive no more protection, the frames being removed for other purposes. They come into use early in June, and are in great demand at very remunerative prices. The Lettuce plants are all gently pulled, so as not to disturb the Carrot crop. *E. W.*

Rose Letty Coles.—Mr. Prior's estimate of this charming Rose must surely have been formed hastily and without having seen it growing. Here it is beautiful, a Madame Willermoz flushed all over with rosy lake, and everything our good friend Mr. Keynes described it to be. So long as Madame Willermoz is grown Letty Coles will be also. *Paul & Son.*

Butcher's Broom (*Ruscus aculeatus*).—In answer to your inquiry (page 82) relative to the use of this plant, I think it highly probable that it is employed for the purpose indicated—in tobacco factories—inasmuch as some few years since a leather tanner in this neighbourhood occasionally asked me for a small bundle of its branches to sprinkle the leather with, and he asserted that nothing else, either in the shape of plant or brush, could so equally sprinkle the water. It may be interesting to add, that although there are several hundreds of this plant growing in the shrubberies here in varied aspects it very rarely fruits, and then only have two or three isolated berries been found, and yet the plants flower profusely. Possibly artificial impregnation might prove potent in the freer production of its fruit. This I purpose trying, and hope to apprise you of successful results. It may also not be generally known that the stiff Rush-shaped stems of this plant afford excellent supports for plant-tying, whether in pots or in borders, and are much superior to deal or other kinds of stakes, one reason being that as the bark retains its primitive green colour no paint is required. For the sweeping out of flues and chimneys a bundle of its branches forms a most efficient brush, and its matured stalks cut into suitable lengths and twisted and bent into shape like hairpins form excellent plant pegs. *William Gardiner, Elington Park Gardens, Warwickshire.*

Anona Cherimolia.—I am trying to grow as a fruit tree (under glass, of course) the delicious Anona Cherimolia of Loxa (Ecuador). I have this spring for the first time got flowers (five) upon my plant, but they did not set. Has it been tried in England, and with what success? What should I do to make them set next year? The blossoms last only a few hours. *T. v. V., an Old South American Traveller.* [Impregnate them with pollen by means of a feather or camel's-hair pencil. *Eds.*]

Irish Yew.—Has any of your readers ever met with a male individual of the Irish Yew? I never did. Two large female specimens I have bear every year numerous seeds, although they can be fertilised only by some male common Yews growing a few hundred yards off. These give birth to a numerous progeny, very constant in their habit, which partakes

of both parents. Less fastigiated than their mothers, they make beautiful specimens, very symmetrical, compact, neither so stiff as their mothers nor so straggling as their fathers. Would not the absence of male plants of the Irish Yew prove that it is a mere variety of the *Taxus baccata*, which some authors doubt? *T. v. V., Perck Nursery, near Vilvoorde, Belgium.*

Ants in Meadows.—Coal though coming under the head of a mineral, is, as is well known, of vegetable origin, and therefore having some affinity to vegetation; and petroleum and its products though called minerals oils are also of the same parentage, but having a most peculiar strong odour, any of these oils are splendid remedies against all descriptions of vermin which infest vegetation and the ground. The thing to be guarded against is, not to use it of too great a strength, for even strong manures will kill plants. I would recommend a mixture, say, two wine-glasses of the oil to the bucketful of water, and well sprinkled over the meadow, when I have no doubt whatever a perfect stampede would take place without injuring the grass, and after the first shower of rain all would be sweet again for cattle. This remedy will be found not only the cheapest in prime cost but the most economical in application. *J. F. D.*

The New Strawberry Loxford Hall Seedling.—This is a great improvement on British Queen. It is hardier, very sturdy, and a very free cropper. Fruit large, handsome and highly flavoured; has only to be known to be highly appreciated. *E.*

Naming of Orchids at Sales.—I am sure the remarks made by Sergeant Cox in your paper of Saturday last must have been read by many with great interest and keen feelings of sympathy with the writer. I can fully bear out the statements therein made as to the frequent misrepresentations that are made regarding the plants that are sold at auctions; I could mention several instances where I have been deceived in this way, and many of my friends have had the like unpleasant experience. I know of several cases where persons have bought what they believed to be the valuable *Odontoglossum Alexandræ*, which however has turned out to be the worthless *O. Lindleyanum*; and again, I have bought *Rodriguezia secunda* as *Burlingtonia fragrans*. Now I should like to know on whose authority these names are given? If the importers name them on speculation, giving them the names of the more rare and valuable Orchids, as far as their characters will allow, then I say it is a wilful fraud on the public, and the sooner some means are adopted to alter the system the better for the credit of importers. It is a pity that they do not all adopt the course pursued by certain firms, who will at once replace any plant that has been sold by them, by auction or otherwise, turning out to be different or inferior to the species for which it was sold. Trusting you will use your powerful interest to bring about a better state of things. *G. E. Cox, Leyton, Essex.*

Annuals in Pots.—It may be thought by some a kind of horticultural anachronism to advocate the cultivation of annuals in pots for decorative purposes, but the recent exhibition of annuals at the Royal Botanic Gardens, Regent's Park, by Messrs. James Carter, Dunnett & Beale, serves to illustrate the beauty and usefulness of many of these when properly grown and cared for. Therein lies the secret of so much success, for if the commonest flowers be only carefully tended they will bloom much finer and more effectively than when these attentions are not forthcoming. If any one wished to realise the difference in appearance between annuals properly cultivated and those as usually seen in gardens, they should see them at the flower farms at Dedham or St. Osyth, where they are sown in manured and deeply dug ground, which is kept clean and well hoed during the blooming time. Annuals in ordinary gardens are rarely cared for; they are sown in poor soil, they are invariably left too thickly in groups, and the plants choke each other, so that there is no free development. It is by reason of such neglect that many pretty things have come to be so much neglected. The annuals shown by Messrs. Carter & Co. were sown in pots in early spring in good soil; they were thinned out when requisite, and watered as required, and this is how it was they were so charmingly developed, and so effective when attractively arranged. A selection of those best adapted for growing in pots includes *Acroclinium roseum* and album, the blue and white forms of *Brachycome iberidifolia*, which are dwarf in growth and singularly free of bloom; *Calceola aurea* and *C. coccinea*, very showy; the red, white, and pink *Catchflies*, most profuse bloomers; *Centranthus macrosiphon*, rose, and the white variety; the annual *Chrysanthemum*—all of which have a branching habit of growth, and form excellent heads of bloom; the dwarf *Clarkias*, *Collinsias corymbosa grandifolia*, bicolor, *bartsisefolia*, and *violacea*; *Gilia laciniata*, mauve; and *G. inflora*, pure white; the

red, white, yellow, and silvery Hawkweeds, charming annuals, that deserve to be much more generally grown; the *Kaulfussias*, of which there are four of five pretty varieties; *Limnanthes grandiflora* and *Douglasii*; the very dwarf *Marigolds* of which *anurea floribunda* is such an excellent type; *Mimulus cupreus* Brilliant, a very effective pot and border plant; all the *Rhodanthes*, the value of which is recognised by their being grown for market purposes; *Sphenogyne speciosa*, the dwarf forms of *Silene pendula*, and the charming varieties of *Viscaria oculata*. Some of the latter are peculiarly striking. Some may be disposed to take exception to this list on the ground that it is wanting in many annuals equally suitable for pot culture; this is quite true, but it must be remembered that the selection simply comprises the best found in the collection seen at the Regent's Park. *R. D.*

Roses Duke of Edinburgh, Lord Clyde, and Beauty of Waltham.—Mr. Wm. Paul should rather "have permitted himself" to say, these Roses were raised by my brother, the late Mr. Paul of Cheshunt, and myself, when in partnership as Adam Paul & Son, the said partnership expiring in 1860. This discussion was raised and decided in your columns long ago, and really these old Roses are not worth further fighting about. Rather let the public compare the Roses "raised" by either firm since 1860. *Paul & Son, The Old Nurseries, Cheshunt, N.* [We hope to hear no more of this. *Eds.*]

The Varieties of Calochortus.—The two varieties of *Calochortus venustus* named by Mr. Baker in your last week's number are, I believe, only a small proportion of the varieties which exist, for on picking a few this morning at hazard from different plants I found no two were quite alike, and five or six were quite as different from Lindley's figure as those named by Mr. Baker. I believe that, in a wild state, these plants are reproduced almost entirely from seed, and that the varieties of this species, as well as of *Cyclobothra elegans*, are far too numerous to mention. Several varieties of the latter species have been named by Dr. Regel and others, but out of a great number of bulbs received from many different parts of the Western States I can only find the following, which I think good and distinct species:—

<i>Calochortus venustus</i>	<i>Calochortus Leichtlini</i> , Hook.
"splendens = C. Roezli	<i>B. M.</i> , 5862
"luteus	Gunnisoni
"macrocarpus, a very distinct species, with sepals as long as or longer than the narrow petals	<i>Cyclobothra alba</i> = glaucus pulchella
"citrinus	"elegans. Pursh. = coccurea, Kell. = Maweana, <i>B. M.</i> , 5976
"filicinus, Kell. = umbellatus, Wood = uniflorus, <i>B. M.</i> , 5809	"Bendhami, perhaps only a yellow var. of the last
	"flava

These plants, though able to resist a greater degree of cold than they are likely to get in England, require the protection of a frame to bring them to perfection, as the leaves are produced in winter or very early spring, and if exposed to the weather get much injured. They grow more robustly and more freely if planted out than in pots, and, unless the soil is very warm and dry, they are best taken up about the end of July and kept dry till October before replanting. They seem to make few or no offsets, but in the axils of the branches small bulbs are often formed, and if the weather is hot seed is produced in abundance. A more beautiful class of plants I do not know, and, though the individual flowers do not last long, a great succession is kept up on one plant, and by having a good number of species the bloom is protracted from May till August. I should be glad to know if any other species besides those I have named are in cultivation. *H. J. Elwes, Preston House, Cirencester.*

Phoenix rupicola.—Mr. Thiselton Dyer truly remarks that this is a most interesting plant, but it is something more, for it is so graceful and handsome that it occupies a similar place among Phoenixes to that of *Cocos Weddelliana* among *Cocos*. A few seedlings of it were indeed raised at Kew some time ago, yet it had never been introduced in any quantity so as to be offered in the trade, or to the public generally, until last spring, when I was able to offer seedlings of it at a moderate price. These were raised from seed which I received from India at the end of last year, direct from the district of the River Teesta; and coming from so great an elevation as 1400 feet, it is a most valuable addition to our greenhouse Palms. Besides these seeds from Northern India, I last year received a large supply of seed of this Palm from Calcutta, through the kindness of Dr. King, though probably this seed had been received in Calcutta from the district above alluded to. The illustration in my catalogue, of which a copy was given in your pages, was, as Mr. Dyer states, made from a plant I obtained in exchange from Kew in March last. I thought so highly of this Palm that I was anxious to illustrate it, but my seedlings not being large enough for that purpose I was glad to effect the exchange alluded to, and especially as the plant was one of the

only two good specimens then existing in Kew Gardens. Under these circumstances the reclamation claimed by Mr. Dyer I make with the greatest pleasure. *William Bull.*

The Rose Caddice Fly.—At page ix. of the Supplement to the *Gardeners' Chronicle* for July 7, among other insect enemies there is a notice and figure of the Rose Caddice fly, which, it is there stated, is rare in Britain. I exhibited a specimen at the last meeting of the Scientific Committee at Kensington, but there were so many other things before the committee that I had no opportunity to say much about it, and therefore it may be of interest to put what I know on record here. Like many other rare plants and animals, the Rose Caddice fly, *Lyda inanita*, may be locally abundant, as the ravages it has committed in my garden this season testify. Knowing next to nothing about insects I destroyed a considerable number of the caterpillars, together with their curiously constructed shelters, before I was aware that this insect was supposed to be rare. But on looking more closely at these "cigar-like rolls" I was so struck with their ingenious structure, that the desire to learn something respecting the insect became very strong. Presently I bethought myself of the Rose Supplement, and I at once referred to it for information. But there, with the exception of the figures, I found little, and that little unintelligible, because it runs thus:—"He (Professor Westwood) called it the Rose Caddice fly, from the curious cigar-like rolls, composed of leaves, that it makes for its offspring." As the figures and the score of specimens on my table show, it is the caterpillar that makes it for itself by going round the circumference of the leaflet, so that the toothed edge comes downwards; and the whole is held together and fixed to some part of the leaf by means of delicate silk threads. Unfortunately before I detected them the caterpillars had nearly or quite finished their dwellings, and completely stripped some of my Rose bushes of their leaves. I may explain that I was absent from home during the whole of the month of June, otherwise they would not have remained undisturbed until they had made cigars of all my Rose-leaves. My neighbours on both sides have suffered, but not to the same extent, as they used the syringe in time to destroy the interesting but destructive caterpillars. *W. B. Hemsley, Turnham Green.*

Mrs. Mappin Pelargonium.—Having seen in the *Gardeners' Chronicle* of July 7 an enquiry respecting the origin of the Mrs. Mappin Pelargonium I beg to say that it is not a sport, but a genuine seedling raised by me while living with J. C. Mappin, Esq., Clapham Park, and sent out by Mr. Cannell, of Woolwich. *W. H. Townsend.*

Foreign Correspondence.

TREES AND SHRUBS THAT ARE DECIDUOUS AT BANGALORE.—The following is a list of some trees and shrubs that are deciduous at Bangalore, prepared by Mr. Cameron, Superintendent of the Lal Bagh at Bangalore, with added notes by Colonel Puckle, late Director of the Government Garden there:—

Bignonia xylocarpa (Tamil, Vandencarni).—A handsome tree. The flowers are produced before the young leaves at the ends of the branches, and are slightly fragrant. This species is remarkable for the length of the seed-pod. (The young foliage is very graceful.) At rest: December, January, February.

***Tecoma stans*.**—A large shrub, pretty while in flower, but becoming very unsightly in a deciduous state. (It is very hardy, and flowers long and profusely; the seed-pods in an advanced stage render the last unsightly.) At rest: February, April.

Shorea robusta (Tamil, Talura).—The timber which this tree yields is very durable, and is much used for making articles of furniture. At rest: January, February.

Spathodeas (Tamil, Vanga or Panawoodachie Marum).—Large, handsome, ornamental trees. They produce four successions of flowers at Bangalore within the period of twelve months. At rest: February, March, April.

Erythrina indica* var. *alba (Tamil, Muratra Marum).—Produce their flowers before the leaves. These are bright scarlet and white, and are very conspicuous in January and February. (The wood is very soft and light.) At rest: November, December.

Cochlospermum Gossypium (Telugu, Buruga).—This tree is sometimes called Bombyx gossypium. The capsules contain a woolly substance like cotton, but of a silky quality. The flowers appear in advance of the leaves in the month of January. (The yellow flowers made an effective contrast to the masses of the Bougainvillea spectabilis grown over the Lal Bagh wall. There is a row of them behind it that produces the effect.) At rest: November, December.

***Poinciana regia*.**—The compound bipinnate leaves of this graceful tree are so finely divided that the foliage presents the appearance of a huge and well-clothed Tree Fern. The species was first introduced from the West Indies, and has become naturalised to India. The flowers, which are very showy and sportive, precede the leaves. (See separate memorandum.) At rest: January, February, March.

P. pulcherrima (Tamil, Mylehoney).—Is a large shrub, which keeps flowering in succession for six or eight months in the year. At rest: December, January, February.

Ficus religiosa (Telugu, Raghie).—The Peepul is too well-known to need a description. (The Peepul and the Neem are planted in marriage with certain ceremonies in connection with serpent worship.) At rest: February, March.

Michelia Champaca (Tamil, Sinapungie Marum).—This tree is figured in Loudon's *Encyclopedia of Plants* and other books as being evergreen, but it is not so here at Bangalore. (The flowers are very sweet, sometimes overpowering in their fragrance.) At rest: November.

Trewia nudiflora (Mal., Canchi).—A large tree. The round fruit or berries, which are very plentiful, are continually falling from the trees for six weeks or more in April and May. (The pollen from the numerous flowers is profusely shed.) At rest: November, December.

Egle Marmelos (Tam., Vilva Marum).—A tall thorny tree, commonly called the Bael of India. The fruit is large and somewhat Pear-shaped, and adheres to the tree during the absence of its leaves. (The pulp of the fruit is accounted a remedy for dysentery.) At rest: March.

Pongamia glabra (Can., Hoongay).—A middling-sized tree, with a smooth shining foliage, somewhat resembling the Beech. An economic plant. (The dullish purple flowers are produced in great numbers in April, and have a pleasing effect. The young foliage is of an exquisite delicate Apple-green, and brightens up the landscape charmingly.) At rest: January, February.

Tectona grandis (Can., Thayacatha Mara).—The Teakwood is generally admitted to be the best, or most durable, in India. The foliage also supplies a red dye. (It produces masses of sober-tinted flowers in May or June.) At rest: February, March.

Anona cherimolia (Tam., Ram sita Marum).—This is a species of the Custard-Apple, which has been introduced from South America; the tree thrives exceedingly well at Bangalore, but does not bear fruit. At rest: April, May.

Cedrela Toona (Tam., Toon Marum).—A handsome tree, the timber is used for making articles of furniture. It has the appearance of inferior Mahogany. At rest: November, December.

***Poinsettia pulcherrima*.**—This shrub has also been introduced from Mexico, but has become quite acclimatised to this country. The crimson terminal bracts and yellow flowers are very showy, and generally appear before the young leaves. (There is also a white or straw coloured variety. Both are profuse bloomers, the first-named the more so, and very hardy. They will stand any amount of hacking about or rough treatment. On a well-kept lawn the effect of the crimson bracts is very striking.) At rest: January, February, March.

Bignonia suberosa (Can., Cork Mara).—A tall, straight-growing tree; the bark is soft and spongy, which may account for the erroneous name of Cork tree, commonly applied in this district. The flowers, which are numerous and very fragrant, appear before the leaves. (The young foliage is very graceful.) At rest: January, February.

Cassia Fistula (Tamil, Ronnay).—A small tree with pretty yellow flowers, disposed on terminal racemes, drooping like the Laburnum. (The flowers are in much larger racemes than in the Laburnum, some fragrant. They appear before the foliage, and present a general mass of colour, which if properly disposed is most effective.) At rest: December, January, February.

Asadirachta indica (Can., Ravena Mara).—The Neem tree is valuable for medicinal use, and also for economic purposes. The bark is sometimes used as a substitute for Cinchona. The timber is very durable, and will resist the attacks of insects on account of its bitter taste. (The flowers in the hot weather in March are abundant, lilac-coloured in two tints, and have the fragrance in the early morning like those of the European Lilac.) At rest: January, February.

Plumeria acuminata (Can., Shavugaanul Mara).—A soft-wooded small tree, spreading habit, having blunt truncate branches and white and yellow flowers, very fragrant, often overpoweringly so. They precede the leaves. A native of the East Islands. At rest: December, January, February.

Ochroma Lagopus (Can., Burigatha Mara).—This is a West Indian tree, the branches divaricate, from the summit. The wood is very soft and tender, so much so that it is sometimes used instead of corks to nets, &c. At rest: January, February.

Bignonia chelonoides (Can., Padric Mara).—A large

tree, generally figured as being evergreen; the timber is very hard. It is called Ironwood. Flowers profusely in March. At rest: February.

Lagerstromia regina (Mal., Adamboe).—A very hand some tree. The flowers are disposed in large terminal panicles, purple, very showy. The wood is valuable for its durability. (The tree in April appears covered with these delicately coloured blooms, which make an impressive display. There are several varieties.) At rest: January, February.

***Holmskioldia sanguinea*.**—An attractive shrub, with bright scarlet flowers, in a membranaceous round spread calyx, of a dim red colour. (A free flowerer, but the colour is dingy.) At rest: December, January.

Bauhinia elata (Can., Ranchvalada Mara).—A small tree, the flowers are large, streaked purple and white alternately. At rest: December, January.

Brassia longifolia (Can., Ippé Mara).—Is locally called the "Ippé," or "Elopie;" is a valuable economic plant, as almost every part is used for some medicinal or economic purpose. (The flowers are very numerous in February, and of a very strong scent, so much so that even their shade at that time of the year is avoided as camping ground. A spirit is distilled from them.) At rest: December, January.

Erythrina glauca (Can., Marjeep Mara).—A small tree, stem and branches prickly, flowers copper coloured; introduced from South America. At rest: February.

Wrightia antidysenterica (Can., Beppaulay Mara).—A small tree, with white flowers; the (follicles) fruits are formed in pairs, and adhere together at the apex. This plant furnishes the official Connessi bark, used in fever and diarrhoea. (The wood is hard and white, and used for inlaying work.) At rest: December, January.

***Meyenia erecta*.**—A very pretty shrub, which thrives well at Bangalore; the flowers are blue, and produced freely four and five times in the year. (It can be kept trimmed to almost any shape in single specimens, or pruned into a low ornamental hedge. There is a white variety, *M. alba*.) At rest: February, March.

Cassia florida (Can., Tagasi Mara).—An introduced species. (The flowers are a dull yellow. It is a very quick grower, but rather a sombre looking tree. It is locally said to be only of twenty-one years' duration of growth.) At rest: February.

Tamarindus indica (Can., Hoonesey Mara).—The Tamarind is deciduous only for a very short time, but that it is so is quite perceptible. (The branches, however, are rarely, if ever, bare of leaves, for the young ones vigorously push forward, and the bright green foliage, of a very delicate colour, is very striking, even before the last year's growth has fallen.) At rest: March.

Reports of Societies.

Ipswich and East Suffolk Horticultural: July 5.—This Society held its first annual meeting on the 5th, in the small but picturesque grounds of the Lower Arboretum, which from their close proximity to the town are well adapted for purposes of this kind. The weather, as usual, although favourable in the morning, turned out adverse during the afternoon, when several peals of thunder broke forth and rain descended heavily just at the time shops were closing and an influx of visitors was expected to see the show or attend the promenade concert to be held in the evening. Such a run of ill-luck as that which this Society has met with for years past appears to have had a most discouraging effect, as the show and wet days have become so associated that few from a distance venture to attend, and exhibitors, too, from some cause or other, are dropping off to such an extent as to render the meetings much less attractive than formerly. This is to be regretted in a large thriving place like Ipswich, with a population of over 50,000, and surrounded as it is by large gardening establishments, besides those of well-to-do tradesmen, who, to their credit, are now its principal patrons and supporters, and to whom therefore the greater share of the prizes fell. In the plant department the contest all through laid between the gardeners of E. Packard, Esq., F. Fish, Esq., F. Limmer, Esq., and Messrs. Gilbert, of St. Margaret's Nursery, who all showed some excellent specimens in the several classes to which they contributed. For six stove and greenhouse plants, E. Packard, Esq. (Mr. Payne, gr.) was 1st, with a fine collection containing two grand Allamandas, *Stephaotis floribunda*, *Bougainvillea glabra*, *Trachelospermum jasminoides*, and *Clerodendron fallax*. The 2d prize fell to Messrs. Gilbert, who had a fine plant of *Erica Parmentieri rosea*, and some well grown *Vincas*. For eight fine-foliated plants, F. Fish, Esq. (Mr. Carey, gr.) took 1st honours with a highly meritorious lot, the finest of which were two huge well-coloured *Caladiums*, Prince Albert Edward and bicolor splendens, two *Crotons*, and a fine specimen of *Adiantum Farleyense*. Messrs. Gilbert came 2d with a nice clean collection, containing *Alophia alba excelsa*, *Areca lutescens*, *Enterpe edulis*, *Maranta zehrina*, and *Pandanus Veitchii* and *utilis*. In the class for six exotic Ferns, Messrs. Gilbert were 1st

with a superior-looking lot, having a fine plant of *Gymnogramma chrysophylla*, *Davallia pyxidata*, *Cibotium regale*, and *Alsophila excelsa*. The 2d prize six were contributed by F. Fish, Esq. (Mr. Carey, gr.), who showed all *Adiantums* of choice kinds, such as *Farleyense*, *scutum*, *concinnum latum*, and *trapeziforme*. For the best specimen plant, E. Packard, Esq. (Mr. Payne, gr.), was 1st with a huge, clean, well-flowered *Trachelospermum jasminoides*; and F. Fish, Esq., 2d, with a good *Clerodendron Balfourianum*. Among plants for table decoration the 3d prize lot were the most attractive, but they lacked size, or they would have stood in a different position, on account of the choice things the collection contained, such as *Cocos Weddelliana*, *Aralia Veitchii* and elegantissima, and *Reidia glaucescens*, all of which are perfection for that kind of work. These were contributed by the Messrs. Gilbert, and the 1st prize lot, by F. Fish, Esq. (Mr. Carey, gr.), who showed highly coloured *Dracenas* and *Crotons*. F. Limmer, Esq. (Mr. Latter, gr.), a new exhibitor, staged some good *Coleus*, and some seedling *Gloxinias* of extraordinary size and merit, having erect flowers of great substance that measured from 3 to 3½ inches across, obtained from Veitch's celebrated strain.

The above contains all that is noteworthy in the plant department. In that of cut flowers the *Roses*, as usual at this time of year, formed the principal feature, although these were not nearly so fine as we are accustomed to see them from the growers who contributed on this occasion. Mr. B. R. Cant, of Colchester, showed the best twenty-four, the most attractive among them being *Miss Hassard*, of *Jules Margottin* type and form, but of a lovely bright flesh colour; and in those of older kinds *Xavier Olibo*, with its rich dark tint and shell-like petals, was most conspicuous; the *Baroness Rothschild*, *Edward Morren*, and *Marquis de Castellane* likewise figured well, as they always do in a stand of cut flowers. Mr. Mill, gr. to Lord Rendlesham, came 2d in this class, and Mr. Lavelly, of Whitton, 3d. In twelves the Rev. Hugh Berners, of Harkstead, was 1st, and Mr. R. Keen, gr. to J. G. Shepherd, Esq., of Campsey Ashe, 2d. As usual the Messrs. Gilbert were 1st for herbaceous cut flowers, and carried all before them for table decorations and bouquets, each of which contained choice things, and showed great taste in their arrangement. Mr. Mill, gr. to Lord Rendlesham, was invincible in the class for button-hole bouquets, which were made up of choice *Orchids* that beggared those beside them.

Fruit, as might have been expected, made but a poor show, but what there was was good, especially the *Grapes* contributed by Mr. Mill, which were highly coloured, well finished, large bunches of *Black Hamburg*; and Mr. Blair, of Shrubland, showed *Duke of Buccleuch* from pot plants, rather small in berry for that kind, but of a rich amber tint, and to which the 1st prize was awarded, as was also that for the collection of fruit, and the best *Pine*, a fine, well-swelled *Queen*, weighing 5 lb. Mr. P. Boreham, gr. to — Skinner, Esq., at The Chantry, showed a fine dish of *Lord Napier Nectarine*, a most valuable early kind, large in size and highly coloured; and Mr. Blair the finest *Peaches*, *Royal George*, still one of the very best for forcing. *Bush fruit* is very backward, and only a few dishes were shown, but *Strawberries* were well represented, with *British Queen*, as usual, taking the lead for flavour. ♀. S.

Tunbridge Wells Horticultural: July 6.—As usual, this exhibition was held in the grounds at the rear of the new public hall, while the table decorations, fruit, and cut flowers found a lodgment in the hall. The productions staged in its exterior made a show of themselves. Foremost was the fruit, which was admirably represented, especially in the class for three bunches of *Black Grapes*. The best, and very finely finished examples of *Black Hamburg* they were, came from J. Deacon, Esq., Mableton Hall (Mr. A. Henderson, gr.), while R. Gostling, Esq., Bishops Stortford (Mr. C. Tyler, gr.), and P. C. Hardwick, Esq., Hollanden Park, were placed equal 2d, the former with remarkably fine *Black Prince*, the latter with *Black Hamburg*. There were something like sixteen exhibitors. In the class for three bunches of white *Grapes* G. Sanders, Esq., Beechwood (Mr. J. C. Mundell, gr.), was 1st, with fine *Muscad* of *Alexandria*; T. Holman, Esq., Hawkhurst (Mr. H. Blundell, gr.), being 2d with the same variety. Foster's Seedling was well shown by Mr. A. Henderson. With three varieties of *Grapes* other than *Black Hamburg* and *Muscad*, Mr. J. Staples, The Gardens, Capestead Place, was 1st with *Gros Colman*, very fine; Lady Downe's and *Buckland Sweetwater*; Mr. C. Tyler was 2d, with *Trentham Black*, *Black Prince*, and *Buckland Sweetwater*. *Royal Muscadine*, *Muscad Hamburg*, *Black Alicante*, and *Golden Champion*, were also shown in this class. *Pines*, *Peaches*, and *Nectarines* were fairly well shown, and there was an abundance of *Melons*—one in particular, a green-fleshed variety, named *Exquisite*, appeared to have attained to perfection in *Melons*. *Strawberries* and *Cherries* were very good, and the former numerously

represented—the best was *James Veitch*, from Mr. T. Worfold, Colhurst Gardens, Horsham. Sir J. Paxton, Dr. Hogg, Keens' Seedling, *Empress Eugénie*, and Sir C. Napier, were very good. *Cucumbers* were numerous and good, and baskets of vegetables also. The best collection of fruit came from J. Goldsmid, Esq., M.P., Tunbridge (Mr. H. Hopgood, gr.).

Roses were numerously shown. In the open classes Messrs. J. Mitchell & Sons, Pittdown Nurseries, took the lead with some fine flowers. In the amateur classes fine blooms came from F. B. B. Atkins, Esq., Capt. Christy, J. Ridout, Esq., and H. Benstead, Esq. Cut blooms of stove and greenhouse plants were good: the stands of wild flowers charmingly set up, and the table decorations as usual very good indeed. Mrs. Seale, Sevenoaks, was again to the fore with some light and elegant designs of great merit. A collection of named wild flowers from Miss Cox, Redleaf, was an admirable production, as instructive as it was good.

Space will not admit of doing full justice to a provincial show that comes near to rivalling York, Leeds, Manchester, &c. Plants are invariably a great attraction at Tunbridge Wells, though this season they fell a little short of their average merit. The best group of eight came from Messrs. Balchill & Nell, Brighton, and comprised a magnificent *Bougainvillea glabra*, *Allamanda Hendersoni*, *Dipladenia amabilis*, finely coloured; *Erica Paxtoniana*, *E. ampullacea Barnesii*, and *Stalice imbricata*. 2d, W. Spottiswoode, Esq., Coombe Bank (J. Bolton, gr.), who had some good plants. The best six came from Messrs. Golding & Co., Hastings. *Fuchsias* might have been better; *Pelargoniums* of all classes were scarcely up to the usual mark; *Gloxinias* and *Achimenes* were unusually fine.

Of foliage plants there was a good display, and a fine effect might have been secured in the big tent had the exhibits been arranged with judgment and taste. A very fine group of eight fine-foliaged plants came from Messrs. Balchill & Nell, consisting of *Croton pictus*, *C. Weismanni*, very fine; *C. undulatus*, *Phormium tenax variegatum*, *Latania borbonica*, *Dion edule*, *Cycas revoluta*, very fine; and *Astrocaryum mexicanum*. Mr. Johnstone, gr. to the Marchioness of Camden, was 2d, with some fine plants, including a magnificent *Latania borbonica*. *Ferns*, *Begonias*, *Caladiums*, *Coleus*, &c., were to the fore in good character. Would that space allowed of more minute details respecting so many good exhibits. (From a Correspondent.)

Enfield Horticultural: July 11.—The exhibition on this occasion was held in the park, Chase Side House, the residence of P. Twells, Esq., M.P., which, with the pleasant and neatly kept grounds adjoining, are in every way adapted for a floral gathering. The show may be said to consist wholly of the productions of local exhibitors, who came out in a way highly creditable to the gardening capabilities of the neighbourhood, not only in the plants, flowers, and fruit grown under glass, but also, considering the adverse season, in *Roses* and vegetables. Several special prizes were offered by gentlemen in the neighbourhood, which brought out the best plants. Special prizes given by F. C. Adams, Esq., and H. J. Adams, Esq., for a group of not less than twelve plants: 1st, Mr. Wilson, gr. to Mrs. Adams, showing a good dozen, in which a large specimen of *Clerodendron fallax*, *Woolley's* dwarf variety of *Sobralia macrantha* (finely flowered), *Oncidium macranthum* and *Cattleya gigas* were intermixed with variegated and other fine-leaved plants; Mr. Pratt, gr. to H. Barry, Esq., who was 2d, had a nice group, consisting of *Palms*, *Dracenas*, *Ferns*, and *Crotons*; 3d, Mr. Shaw, gr. to P. Twells, Esq., with about a score of nicely grown thriving young specimens of fine-leaved plants. The mistake here made of not limiting the plants in the class to a fixed number is a very common one at provincial shows, but it is very objectionable, as the awards of the judges cannot be based alone, as they always should be, on the quality of the competing collections, but numbers also have to be taken into account, which frequently makes the decisions difficult and unsatisfactory to all concerned.

Prizes given by F. S. Foley, Esq., for six stove and greenhouse plants, in flower—1st, Mr. Wilson, who had *Ixora alba* and *Dipladenia amabilis* in fine condition; 2d, Mr. Shaw, in whose group was a large and beautifully flowered *Stephanotis floribunda*. Prizes given by G. Batters, Esq., for three flowering and three fine-leaved plants—Mr. Wilson was also 1st, Mr. Gooderham, gr. to E. Ford, Esq., 2d. Prizes given by J. Collins, Esq., for twelve dinner-table plants, in 6-inch pots, shown in pairs—1st, Mr. Wilson, whose plants were just as they ought to be, neither too large nor too massive. Nothing but naturally slender, thin-barked subjects are fit for this purpose. Mr. Wilson's dozen was composed of pairs of *Chamaedorea graminifolia*, *Reedia glaucescens*, *Prenanthes hybrida*, *Abutilon vexillarium variegatum*, small drooping standards, *Dracena Guilloylei*, and *Adiantum gracillimum*. We give the names, for, excepting the *Fern*, which is a little too formal in

outline, these were a selection of the best plants for table decoration we have seen for some time. Mr. Pratt was 2d. In the class for four stove and greenhouse plants Mr. Wilson took the lead, showing amongst others a finely flowered *Ixora amabilis*; Mr. Fratt, 2d. Six stove and greenhouse *Ferns*.—1st, Mr. Wollacott, gr. to F. S. Foley, Esq.; 2d, Mr. Farron, gr. to G. Batters, Esq. *Achimenes* were remarkably well done. Mr. Tonge, gr. to J. S. Law, Esq., who was 1st, had in an even profusely flowered lot beautiful examples of *Mauve Queen*, *longiflora alba*, and *longiflora major*; Mr. Wilson 2d.

Six fine-foliage plants.—1st, Mr. Wilson; 2d, Mr. Wollacott. Six *Begonias*.—1st, Mr. Tonge; 2d, Mr. Lowe. Six *Caladiums*.—These were well shown, stout and compact in growth, and the kinds sufficiently varied. 1st, Mr. Wilson; 2d, Mr. Wollacott. Cut Flowers: *Roses*.—For Mr. Rumsey's prize for twelve, Mr. Lowe was 1st. In the class for twenty-four, Mr. Cornish, gr. to J. Abbiss, Esq., 1st; Mr. Lowe, 2d. Twelve: 1st, Mr. J. Green, gr. to J. Warren, Esq.; 2d, Mr. Wilson. Six: 1st, Mr. Farron; 2d, Mr. Medcalf, gr. to Mrs. Harrison. Twelve bunches stove and greenhouse flowers.—1st, Mr. Wilson, showing in his box the singular *Aristolochia orthoccephala*; 2d, Mr. Gooderham. Twelve bunches hardy flowers.—1st, Mr. Cornish; 2d, Mr. Farrow. Device of cut flowers (competition confined to ladies).—1st, Mrs. Downing; 2d, Mrs. Stearns.

Fruit.—Eight dishes: 1st, Mr. Farrow, having amongst others nice *Buckland Sweetwater* and *Black Hamburg Grapes*, *Early Albert Peaches*, and *Murray Nectarines*; 2d, Mr. Pratt. Two bunches *Black Grapes*: Mr. Wilson was 1st, showing well finished *Hamburgs*; Mr. Green 2d, with larger bunches a little deficient in colour. Two bunches white *Grapes*: Mr. Farrow, 1st; Mr. Green, 2d. Mr. Farrow was 1st for a dish of *Peaches*, for a dish of *Nectarines*, and also for a *Melon*. Mr. Shaw took 1st for *Cherries*, and likewise for two dishes of *Strawberries*.

Roses in considerable quantity and in fine condition were contributed by Messrs. Paul & Son, The Old Nurseries, Cheshunt; W. Paul & Son, Waltham Cross; Mr. John Fraser, Lea Bridge; and Mr. W. Rumsey, Waltham Cross.

Ealing, Acton, and Hanwell Horticultural: July 11.—Year by year this Society has steadily grown until it is now able to exhibit one of the best shows of cottagers' produce found within 50 miles of London. A great many special prizes are given by the residents and tradesmen, the latter generally in kind, ranging from a sewing machine to a mug. All these prizes are competed for most keenly, as well as the *Baroness de Rothschild's* and Mrs. Walpole's special prizes for the allotment and cottage gardens—these two ladies giving between them twenty prizes, ranging in value from 25s. to 5s. Prizes are also offered for the best kept flower garden.

The exhibition of cottagers' produce surpassed this season all expectations, so thoroughly good was it. In some of the classes for *Potatoes*, *Peas*, *Broad and Longpod Beans*, autumn sown *Onions*, there are from twenty to thirty entries, and eight prizes are given in each, with the addition of extra prizes. Punnets are found for the exhibitors to stage their produce in, which gives the exhibition tables an orderly and neat appearance.

The open classes are confined to the residents of the districts, but some remarkably good plants are staged by H. J. Atkinson, Esq., Gunnersbury House (Mr. Hudson, gr.); J. S. Budgett, Esq., Ealing Park (Mr. Edwards, gr.); C. O. Ledward, Esq., The Elms, Acton (Mr. J. Hepper, gr.); E. M. Nelson, Esq., Hanger Hill House (Mr. W. Bunn, gr.); Miss Wood, Hanger Hill (Mr. Fountain, gr.); and T. Nye, Esq., Castle Hill (Mr. J. Hart, gr.). The prizes are not large, but they are well competed for. In Mr. Hudson's group of six foliage plants, to which the 1st prize was awarded, were splendid examples of *Croton pictus*, *C. variegatus*, *Alocasia Lowii*, and *Areca lutescens*. The best six flowering plants came from Ealing Park, the best six stove and greenhouse plants from Mr. Hudson. In the same classes fruit and cut flowers were well done, generally by the exhibitors above.

There were also divisions for amateurs, meaning thereby one who does not constantly, but only occasionally, employ a gardener, and single-handed gardeners, or those who have only occasional assistance. These divisions are necessary in order to put the many exhibitors on a footing of equality.

Considerable interest always attaches to the handsome special prizes offered by the committee for forty-eight varieties of *Roses*, three trusses of each. On this occasion there was a keen competition—Mr. C. Turner, Royal Nursery, Slough, being 1st, Mr. B. R. Cant, Colchester, 2d; and Messrs. Paul & Son, Cheshunt, 3d. An extra prize was awarded to Mr. G. W. Piper, nurseryman, Uckfield. The flowers were very good and fresh. The varieties were those which have already been given in connection with *Rose* shows. Some special prizes were also offered for

amateurs' Roses, and a large number of blooms competed.

The show took place in the gardens of the Vicarage at Ealing, which contains some striking trees, among them a very fine example of *Allantus glandulosa*.

Woodbridge Horticultural: July 12.—This Society held its annual meeting in the Abbey grounds, and, as usual, was well attended both by exhibitors and visitors, who came from afar, tempted by the fine day and the excellent displays of fruit and flowers that are always got together on these occasions. It would be well for the interests of horticulture did other towns carry it out in the same spirit as Woodbridge; for, although a small place, the exhibition is scarcely second to any in the provinces. This year it was more attractive than ever, as, in addition to the local exhibitors, the Messrs. Veitch sent a van-load of plants from London, most of which were rare and of great value. The collection contained many choice Orchids, new Crotons and Dracenas, that put all the older well-known kinds in the shade, *C. Mortii* and *tortilis* being especially remarkable for the rich colouring of their leaves. Two new Begonias of the tuberous-rooted section, named *Acme* and *Vesuvius*, were particularly showy, having very large brilliant flowers that would set a greenhouse quite aglow, as they did that part of the tent they were stood in. Besides the above there were many other plants too numerous to name or particularise, but all of such sterling worth and beauty as to set growers longing for their possession. None of these were for competition, but a special prize was awarded. Some good stove and greenhouse plants were shown, as also others of ornamental foliage, the prizes for which were awarded the same as at Ipswich. For Roses, Mr. Nichol, gr. at Drinkstone Park, outdistanced all competitors, taking 1st in all the classes, and thus beating Mr. Cant, of Colchester. The show of Grapes was better than is generally seen, Mr. Will, gr. to Lord Rendlesham, contributing some well-finished bunches that placed him at the head of the list. Cherries, Currants, and Strawberries were plentiful, and remarkably fine. Among vegetables, Cullingford's *Magnum Bonum* Peas appeared the favourite, as, excepting one dish of Veitch's Dwarf Marrow, they were all of that variety. *J. S.*

Tunbridge Horticultural: July 18.—This exhibition took place in the grounds of Tunbridge Castle, the residence of Mrs. Senior, which is quite in the heart of the town. The Castle itself, or so much of it as now remains, is full of historical associations, and the grand old keep, with its massive gateway, still forms a wing of the residence.

The show formed another of the series for which the county of Kent is so famous. On the whole the productions were good, and it was said to have been the best exhibition ever held in Tunbridge. The staging was somewhat roughly done in the plant tent, a better plan of general arrangement would have greatly enhanced the appearance of the plants, and a better system of staging the groups.

Stove and greenhouse plants were shown in classes of eight and six. In the former W. Spottiswoode, Esq., Tunbridge (Mr. J. Bolton, gr.), had examples of *Clerodendron Balfourianum*, *Anthurium Scherzerianum*, *Erythrina crista-galli*, *Stephanotis floribunda*, *Clerodendron fallax*, *Allamanda Hendersoni*, *Dipladenia amabilis*, and *Franciscea calycina major*; 2d, H. B. Mildmay, Esq., Shoreham Place (Mr. J. Burt, gr.). The best six came from E. Cazalet, Esq., Fairlawne (Mr. G. Fennell, gr.), who had *Allamanda Hendersoni*, *Bougainvillea glabra*, *Stephanotis floribunda*, *Anthurium Scherzerianum*, *Kalosanthes coccinea*, and *Begonia Vesuvius*. Mr. Bolton was 2d, his best plants being *Cassia corymbosa*, *Allamanda grandiflora*, and *Clerodendron fallax*.

The leading exhibitor of foliated plants was J. Deacon, Esq., Tunbridge (Mr. A. Henderson, gr.) who had the best six, consisting of *Pritchardia pacifica*, *Dasyliroton longifolium*, *Croton angustifolius*, *Dion edulis*, *Pandaus ornatus*, and a fine piece of *Cocos Weddelliana*. Mr. J. Bolton was 2d, The best four also came from Mr. A. Henderson. Mr. Bolton had the best six exotic Ferns, and Mr. J. Burt the same number of *Caladiums*—Albert Edward, Meyerbeer, Langri, Donizetti, and bicolor splendens were in good condition. P. C. Hardwick, Esq., Tunbridge (Mr. G. Goldsmith, gr.), also had some nice plants. *Begonias* in flower, being somewhat unusual, had something more than ordinary interest. The group of six shown by Mr. J. Bolton, to which the 1st prize was awarded, consisted of *Cheloni*, *intermedia*, *Royalty*, very fine; *Stella*, *Paviflora*, and one other. *B. weltoniensis* and hybrids of this type were also shown. *Fuchsias* were well shown by Mr. T. Baker and other, and variegated *Pelargoniums* were finely grown and coloured. Prizes were also awarded for groups of plants arranged for effect. Cut flowers included Roses, and here Messrs. Mitchell & Sons and Mr. W. Seale were the principal exhibitors; and the table decorations were remarkably good.

The show of fruit, though not extensive, was decidedly good. The best collection of six dishes came from G. A. Dodd, Esq., Ashford (Mr. W. Wilson, gr.). Miss Bashford, Tenwell, and A. Henderson also exhibited, receiving prizes in the order in which their names are given. Some very fine Stanwick *Elrage Nectarines* were shown by Mr. J. Bashford. Vegetables were well shown, and the classes for nine and six kinds brought together some excellent kitchen garden produce. A tent was set apart for cottagers' produce, which was generally of a satisfactory character. A remarkably fine example of *Hymenophyllum tunbridgeense* was shown by Dr. Angier, Tunbridge, growing under a glass shade, and in the best of health.

Law Notes.

TRAPPING TRESPASSING DOGS AND CATS.—The case of *Daniel* (appellant) *v. Jones* (respondent), recently decided before Lord Coleridge and Mr. Justice Lindley, is of much importance to owners both of property and also of domestic animals that are inclined to stray and do mischief. Mr. Daniel is a member of the bar, and resides in a suburban house, with a garden at the back. He has a stable, which he did not use, and sublet as a carpenter's shop. The tenant, Jones the respondent, had a dog; this animal was in the habit of forcing his way through the hedge of Mr. Daniel's garden, which was fenced off from the path leading from the main road to the stables. The dog proved a great nuisance to Mr. Daniel, and did a good deal of harm to his garden. He accordingly gave notice to Mr. Jones that he contemplated laying poison in his garden, and that it would be unsafe for the dog to continue its habits of trespassing. Mr. Jones, however, took no steps to restrain the dog, and before long it again trespassed, and partaking of the poisoned delicacy came to an untimely end. Mr. Jones took criminal proceedings against Mr. Daniel, and summoned him under the "Malicious Injuries to Property Act" (24 & 25 Vict., cap. 97). The case was heard before Mr. Paget, the stipendiary magistrate, who, taking a strangely prejudicial view of the case, convicted Mr. Daniel in the full penalty of £20 and costs. From the decision Mr. Daniel appealed.

Now, the essence of a charge of this description should be, that the alleged act is in the first place unlawful, and in the second malicious. The statute is, as characterised by Lord Coleridge, a "highly penal" one, and is chiefly directed against arson, wilful damage to property, and such-like offences. In the opinion of the Court the mere facts that Mr. Daniel had been acting in defence of his own property, and that he had also given full notice of his intention to lay poison, were amply sufficient to dispel any theory of "malice;" and upon that ground, without going deeper into other aspects of the case, the Court at once quashed the conviction. For this there was ample precedent. It has been laid down, in the case of *"Bryant v. Eaton,"* that if a landowner sets a trap upon his own premises, laying it upon a stone upon which cats are in the habit of alighting when trespassing upon his premises, he is not liable. So long as animals trespass spontaneously their owners must bear the blame. Also there are the cases of *"Irving v. Crump"* and *"Deane v. Clayton,"* which show that if a dog-spear be set in a cover, and not in a regular path, and a dog stray and get impaled upon it, the landowner is not liable for damages.

On the opposite side of the question, it must be remembered, that while persons may protect their property, they must not expressly entice animals on to their premises for the purpose of destroying them. In *"Townsend v. Wathen"* it was laid down that where an owner of land lays "strong-scented" meats upon his own land within reach of a highway, or of any place upon which such domestic animals have a full right to be, and they are thereby enticed to traps baited with these meats, he is liable for damages; nor is it any adequate defence for him to plead that his traps were set solely for the purpose of destroying vermin (*vere natura*). It would be a case, of course, for a jury whether, upon the evidence adduced, the animals trespassed spontaneously or by reason of the allurements of the baits. If they trespassed spontaneously in the first instance, then the fact that they were

enticed by a bait when once they came within range of it would not make the landowner liable. In Mr. Daniel's case it seems pretty clear that the dog was in the habit of trespassing spontaneously, and that the poisoned meat which was laid down was in no way the primary cause of its entering the garden.

The Court, in quashing the conviction, was content to confine itself to the question of malice, and carefully abstained from offering any opinion whether Mr. Daniel's act had been of itself "lawful," as regards the provisions of the "Poisoned Flesh" Act, for the summons had not been taken out under that statute. It is forbidden to lay poisoned meat in an exposed place, or, in fact, in any other than a building or "enclosed garden." Now, in one sense this garden was enclosed, for it was fenced all round; in another it was not enclosed (as against a dog), for the dog easily forced its way into it. All depends whether the Act is to be construed as meaning "enclosed" generally or specifically, so that no domestic animal can make its way into it. It would be very problematical whether a garden fenced in with iron hurdles could be called an "enclosed" garden; and if not, then how far is one enclosed that is protected by a fence with holes in it? In *"Stansfield v. Bolling"* a tradesman laid poison behind his counter, which was not shut entirely off from the customers' part of his shop. A dog entered with a customer, was attracted by the smell of the poisoned cheese, and got poisoned. It was held in this case that the tradesman was not responsible. At the same time, until a case shall have come before the superior courts upon the question, what is actually an enclosed garden in the meaning of this Act, owners of property will do well to confine the protection of their property to traps only, and not to run any risk of an infringement of the Poisoned Flesh Act. For it is obvious if no cat or dog can enter, the poison is not needed as protection as regards such animals, and if they can find access, it is possible that the existence of such access vitiates the conditions of "enclosure." The lesson to be learnt by owners of domestic animals is, that if their pets trespass spontaneously, and get trapped, they have no remedy. At the same time, no owner of property may, as explained above, go out of his way to entice on to his premises or property generally animals which otherwise would not have entered upon his lands, and then destroy them. Above all, till the law is more settled upon the question of "enclosure" of a garden, he will do well to abstain from laying poison and will confine himself to traps, if he has necessity for protecting his property. *Agricultural Gazette.*

A DISPUTED SALESMAN'S ACCOUNT.—*Hancock v. Arnold.*—This was an action brought in the Bloomsbury County Court, recently, before Mr. Judge Russell, in which the plaintiff, a salesman in Covent Garden, sued the defendant, a retail greengrocer and fruiterer, to recover the sum of £9 9s., being the balance of account rendered for goods sold and delivered. Mr. M. Lewis appeared as solicitor for the plaintiff; Mr. Charles Williams, solicitor for the defence.

The plaintiff being called, said he had had several business transactions with the defendant, who was a fruiterer, carrying on business at Queen's Crescent, Haverstock Hill, and who had an open account in the market. On the 19th of last December the plaintiff ordered goods to the amount of £7 4s. 10d., and on the following day he bought £9 9s. worth of goods, which he (the plaintiff) saw delivered into the defendant's van, and gave him the particulars of the purchases when they were loaded in the van, and the defendant appeared perfectly satisfied.

John McTurk, a collector in the market, said he had frequently applied for payment, when the defendant said it was inconvenient, but never denied his liability. The evidence as to the delivery of the goods having been proved, concluded the plaintiff's case.

Mr. C. Williams addressed the Court on the part of the defence, urging that his client was a very respectable man, and would not repudiate a just debt, but when he promised to pay the plaintiff's account, he was not aware of an inaccuracy in it, and that he had been overcharged, but this was the case, and he should call upon his client to prove it.

The defendant (called) said he always denied owing the amount sued for, although he was aware that he owed something. He had two accounts from the

plaintiff, and the last was much larger than the former one. He mentioned that fact to the plaintiff, and was solicited by him to look at his books and see his clerk on the subject.

Clifford Forbes (plaintiff's clerk) said he had made a clerical error in the account, which he had explained to the defendant, who had since promised to pay.

Mr. Williams said that after that evidence he could not carry his client's case further.

The learned Judge considered Mr. Williams perfectly right, as it was impossible to say that the defendant, from the evidence before the Court, had not acknowledged his indebtedness; therefore judgment would be in favour of the plaintiff for the full amount claimed, with costs of attorney and witnesses.

TIME THE ESSENCE OF CONTRACT: *Davenport v. Rhodes*.—This, which was an adjourned case, came on for hearing in the Bloomsbury County Court recently, before Mr. Judge Russell. The plaintiff, described as a horticultural decorator of Edgware, sued the defendant, a private gentleman, residing at Highgate, to recover the sum of £20 odd for the erection of a small greenhouse on the defendant's premises.

Mr. M. Lewis (who appeared as solicitor for the plaintiff) said his client had received written instructions from the defendant to erect the greenhouse in question, and imagined that, from the letters he should produce in Court, the action was purely an undefended one.

The letters were put in and acknowledged by the defendant to be in his own handwriting, and subsequently the plaintiff's foreman was called, who proved that the glass and other materials were about to be delivered at the defendant's residence, but acceptance was refused.

The carman of the plaintiff proved the attempted delivery of the goods, when the defendant was most insolent, and ordered the witness to take the work away, but assigned no reason for doing so.—In cross-examination by Mr. Williams the witness said that he was told that the order was given in January last, and was to have been completed by the end of February, but it was in the middle of March that the framework was taken home.

The plaintiff having no further witnesses to call, his case was completed, upon which

Mr. Williams said that this was one of those innumerable cases with which his Honour had to be troubled, and especially so as in this instance he should prove, by the testimony of the defendant and of one or more independent witnesses, that in this case time was to be the *prima facie* evidence of the contract.

The defendant being called, said he was fond of floriculture and horticulture, and, wishing to have a small greenhouse erected, he wrote to the plaintiff, who called and took the dimensions of the glass and work and frames, he (the defendant) agreeing to employ his own builder to do all necessary brick-work.

By the learned Judge.—There was an explicit verbal arrangement that the work was to be complete for stocking in the end of February. The letters produced in Court had no reference to time, but that was understood to be the case by the evidence of his wife and son, who were present when the plaintiff promised to have his work completed by the end of February.

Marian Rhodes, the defendant's wife, and Edward Rhodes, the defendant's son, said they were both in the library in January last, and recollected the defendant telling the plaintiff that the greenhouse must be finished in February, and the plaintiff said it should be done.

This being the case for the defendant, the learned Judge considered that the weight of evidence preponderated on the side of the defendant, who was corroborated by the evidence of his wife and son, whereas the plaintiff's witnesses only went to prove the delivery of the goods without reference to time. No doubt Mr. Williams was right, as in all transactions of this kind time was always considered the basis of a contract, and, therefore, the defendant, at any risk, was right in refusing goods delivered in March which ought to have been delivered in February. Judgment would, therefore, be in favour of the defendant, with costs of solicitor and witnesses.

- July 19.—A dull cloudy day, sunshine at times. Occasional slight rain. Cool.
- 20.—A fine day, partially cloudy. Cool breeze.
- 21.—A very fine bright day. Cool.
- 22.—Fine, but dull and very cloudy till evening, then clear.
- 23.—A dull, cloudy, wet day. Strong breeze.
- 24.—A fine day, partially cloudy. Rain fell in early morning.
- 25.—A fine day, but cloudy and cool. Few drops of rain at night.

LONDON: *Barometer*.—During the week ending Saturday, July 21, in the neighbourhood of London the reading of the barometer at the level of the sea decreased from 29.29 inches at the beginning of the week to 29.25 inches by the morning of the 15th, increased to 29.91 inches by the afternoon of the 18th, decreased to 29.81 inches by the evening of the 19th, increased to 30.05 inches by the morning of the 21st, and was 29.97 inches at the end of the week. The mean reading for the week at sea level was 29.71 inches, being 0.29 inch below that of the preceding week, and 0.28 inch below the average.

Temperature.—The highest temperatures of the air observed by day varied from 73° on the 21st to 61° on the 16th; the mean value for the week was 67°. The lowest temperatures of the air observed by night ranged from 49½° on the 21st to 57° on the 15th; the mean value for the week was 53½°. The mean daily range of temperature in the week was 13°, the greatest range in the day was 23½°, on the 21st, and the least 6½°, on the 16th.

The mean daily temperatures of the air were as follows:—15th, 59°·3; 16th, 57°; 17th, 57°·1; 18th, 58°·8; 19th, 60°·8; 20th, 58°·9; 21st, 59°·1; and the departures in defect of their respective averages were:—3°·4, 5°·7, 5°·6, 3°·8, 1°·7, 3°·5, and 3°·2. The mean temperature of the air for the week was 58°·7, being 3°·8 below the average of sixty years' observations.

The highest readings of a thermometer with blackened bulb in vacuo, placed in sun's rays, were 141¼° on the 20th, 137¼° on the 21st, 136¼° on the 18th, and 131¼° on the 15th; on the 16th the reading did not rise above 68°. The lowest readings of a thermometer on grass, with its bulb exposed to the sky, were 41½° on the 21st and 44° on the 20th; the mean of the seven low readings was 49½°.

Wind.—The direction of the wind was S.W., and its strength moderate. The weather during the week was generally dull, cool, and the sky cloudy.

Rain fell on three days during the week; the amount collected was 0.82 inch.

ENGLAND: *Temperature*.—The highest temperatures of the air observed by day were 73½° at Norwich, 73° at both Blackheath and Cambridge, and 71° at both Hull and Sunderland; at Wolverhampton and Liverpool 65¼° was the highest temperature. The mean value from all stations was 69½°. The lowest temperatures of the air observed by night were 42° at Eccles, and 43° at Sheffield; at Portsmouth 54° was the lowest temperature: the mean from all stations was 48°. The range of temperature in the week was the greatest at Eccles, 27½°, and the least at Liverpool, 13½°. The mean range of temperature from all stations was 21½°.

The mean of the seven high day temperatures

was the highest at Cambridge, 69½°, and the lowest at Liverpool, 61¼°; the mean value from all stations was 65¼°. The mean of the seven low night temperatures was the lowest at Eccles, 49°, and the highest at Portsmouth, 56°; the general mean from all stations was 52¼°. The mean daily range of temperature in the week was the least at Liverpool, 7½°, and the greatest at Cambridge, 17½°; the mean daily range from all stations was 13°.

The mean temperature of the air for the week from all stations was 57½°, being 8° lower than the value for the corresponding week in 1876. The highest value was 59½°, at Norwich, and the lowest 54¼°, at Eccles.

Rain.—The fall of rain during the week was the heaviest in the northern counties. At Bradford it was 2.70 inches, at Eccles 2.39 inches, at Leeds 2.12 inches, and Sunderland 2.05 inches; at Sheffield and Hull three-tenths of an inch only were measured. On Sunday, the 15th, the fall was generally large. The average fall for the week over the country was 1.13 inch. The weather during the week was generally dull and showery, though fine at times.

SCOTLAND: *Temperature*.—The highest temperatures of the air varied from 69° at Dundee to 65° at Aberdeen; the mean value from all stations was 67°. The lowest temperatures of the air ranged between 43° at Dundee and 47½° at Leith; the mean value from all stations was 45¾°. The mean range of temperature in the week from all stations was 21¼°.

The mean temperature of the air for the week from all stations was 57¼°, being 4½° lower than the value for the corresponding week in 1876. The highest was at Dundee and Perth, both 58°; and the lowest at Paisley, 56½°.

Rain.—The fall of rain was generally large everywhere, and varied in amount from 2½ inches at Leith and 2¼ inches at Perth to 1 inch at Glasgow. The average fall over the country was somewhat more than 1¼ inch.

DUBLIN.—The highest temperature of the air was 68½°, the lowest 43°, the range 25½°, the mean 58½°, and the fall of rain 1.04 inch.

JAMES GLAISHER.

Variorum.

FITTONIAS AS WALL CLOTHES.—While admitting to the full beauty of Fittonias, as generally grown, yet the best place for the richest exhibition of the peculiar veining and rare colouring of their beautiful leaves is the surface of a rusticated or roughened wall, where they may be brought near the eye and looked at on a level with it downwards. The Fittonias are most effective when thus placed, though there are no objections to using them for the decoration of higher walls. But the upper surface of the leaf is the richest and best to look upon, and the leaf, unlike many others, grows in richness and beauty the more closely it is examined. The Fittonias also prefer the shady sides of walls. They are most beautiful and most at home on the north side of the walls, and plants if used on the south side or other sunny aspects, must be carefully and rather densely shaded, to bring out their peculiar beauty. It is a peculiarity of the Fittonias and many other variegated plants that their leaf-colouring can only be perfected in a very subdued light. Not only are the colours richer under shade, but the plants become far more robust and strong. The Fittonias also love moisture as much as shade. The roots cling to damp walls, and the branches root at any joint without being detached from the plants, and, altogether, no plant looks more at home on walls than Fittonias. Nor are the flowers to be despised in such positions. Though small and comparatively insignificant, some of the plants should be allowed to bloom, if only for the sake of gaining a little more diversity of stature and of form. The Fittonias are dwarf plants, and the more dwarf varieties are the best for wall-furnishing. Therefore, the best plants to use with them are the more dwarf varieties of Maidenhair or other Ferns, Lycopods of sorts, and *Isolepis gracilis*. The drooping beauty of the latter gives charming green verdure and variety, interspersed with the rich colouring of the Fittonias. But the latter are sufficiently rich and varied in themselves to furnish any amount of wall with green beauty, and an entire wall of Fittonias, in that luxuriance of health and richness of colour which is seldom seen off walls, furnishes one of the richest scenes of wall drapery within reach of cultivators. *D. T. Fish*, in "Flora."

PLAGUES OF SUMMER.—When we talk about the many pleasures of the summer, there is one of its plagues I must say a few words about, for, tiresome as we all have experienced it to be every summer of our lives, it is a subject that is full of interest. What is more common than than to hear people complain of the "midges," that sting them whenever they mean to enjoy a long afternoon in the garden, or an evening

stroll by the river or pool? We all know the "midges" to our cost, but not all of us know much about them, or what strange lives they have led before their last change transformed them into our tormentors. What are called "midges" are the insects, chiefly living in the woods and watery places, which live by sucking the blood and juices of the larger animals. The common gnat is an insect we all know, and one that possesses a most interesting history. The female gnat lays her eggs on the water, placing them side by side, two or three hundred of them, in the shape of a little boat. As the eggs come to maturity they sink deeper; and the grub, when hatched, at last creeps at the bottom of the water. From the beginning of May innumerable larvae of gnats may be seen in stagnant waters, head downwards, breathing near their tails, which are erected to the surface for this purpose. Their heads are armed with hooks, which enable them to seize on the insects and bits of grass on which they feed; and on their sides are four small fins, by the help of which they swim and crawl along. After a fortnight or three weeks, these grubs turn into chrysalids, and through their thin covering the different parts of the future winged insect can plainly be seen. They now breathe more like other creatures, the respiratory tube being altered in shape and placed near the head. These chrysalids do not eat, and are almost always at the top of the water; but on the least motion they unroll themselves from their spiral position, and by means of little paddles plunge to the bottom. After a few days the chrysalid swells at the head and the perfect gnat bursts from its protecting case. The robe which he so lately wore turns into a ship, of which he is the mast and sail. Good fun for him if the weather be still, for then he can soon disengage himself and fly away; if not, a drop of water would upset the little boat and drown the sailor before he could free himself. But once safe and free, off he flies to pursue his prey, both man and beast. The proboscis, or long nose, like the elephant's trunk, is very beautiful in the gnat. It is through this trunk, that it draws the juices on which it feeds. On it are five or six minute little spikes, some sharp-edged, like razors, others with heads like arrows. These little spikes, stuck into the flesh, act like the suckers of a pump. Into the wound caused by these spikes the insect injects a small quantity of liquor, which renders the blood more fluid, and causes irritation. From "Little Folks" for July.

ANNUAL WEEDS.—A curious subject for inquiry by the botanist might be found in the singular characteristic displayed by certain annual weeds in affecting some years more than others, and on the favoured occasions literally cropping the unclean soil with its growth. Thus last year Groundsel made a marvellous growth, and its abundance was generally remarked. On many pieces of ground that had remained uncultivated until late in the season the growth was so thick that the cutting it with a hook was found to be the most expeditious method of clearing it away. This year the same soil is producing but little Groundsel, and a great crop of the white Daisy flowered, well-known in country districts as Morgan. This is most abundant, and almost smothered other weeds with its thick growth. Sometimes we find the land smothered with Shepherd's Purse, at other times Chickweed, at others the red Mayweed, at others Charlock, and so on *ad infinitum*. It may perchance be the case that hitherto these curious facts have only been observed by the unscientific cultivators of the soil, who have mentally made their observations but have not allowed themselves to proceed on from effect to cause. It may be that the soil is full of seeds that lie dormant until some season better favouring the growth of certain kinds sets all within the reach of light and life into germination, but conjecture can hardly get beyond that. The marvellous sustaining power of seeds is evidenced when soil that has not perchance seen the light for thousands of years is brought to the surface and then found to be teeming with life and vegetation, and yet of plants probably identical with those then growing wild around. A field well worthy the scrutiny of an inquiring mind is here open. The subject has been under observation at Rothamsted for many years, and we trust the report on the subject may not long be delayed.

VITALITY OF SEEDS.—At the Middlesex Industrial Schools, Feltham, there may be seen growing a fine breadth of Cabbage raised from seed saved ten years previously. This is a pretty good proof of the vitality of seed of the Brassica family when it is carefully stored. At the same place might be observed a useful illustration of how to make an ordinary greenhouse available for the summer growth of Cucumbers. The house has a span-roof, and has 20-inch shelves running round the sides, and a 3-foot flat stage in the centre. The house is chiefly used to winter bedding plants. As soon as these are cleared out in May, 9-inch boards are fixed round the sides of the stages, and the space inside filled with good soil. The plants have been previously

raised in a small frame, and are then turned out—a row all round the house and two rows down the middle; these are trained to stakes, and soon produce an abundant crop of fruit. One seedling kind, the result of a cross between Telegraph and the Marquis of Lorne, was remarkably good.

A TRAVELLER, in passing through a country in Persia, chanced to take into his hand a piece of clay which lay by the wayside, and, to his surprise, he found it to exhale the most delightful fragrance. "Thou art but a poor piece of clay," said he; "an unsightly, unattractive, poor piece of clay; yet how fragrant art thou! how refreshing! Whence hast thou this fragrance?" The clay replied, "I have been dwelling with the Rose." Shirley Hibberd, in the "Amateur's Rose Book."

"THERE'S a bower of Roses by Bendemeer's stream, And the nightingale sings to it all the day long; In the time of my childhood 'twas like a sweet dream To sit in the Roses and hear the bird's song."

"That bower and its music I never forget, But oft when alone, in the bloom of the year, I think, Is the nightingale singing there yet? Are the Roses still bright by the calm Bendemeer?" Moore.

Enquiries.

He that questioneth much shall learn much.—BACON.

197. PASSIFLORA GRACILIS.—Can any reader oblige the Editors with a few seeds of this Passion-flower?

198. ROSE.—Would any reader of the Gardeners' Chronicle recommend me a good, large, sweet-scented, red Rose to climb against a white house, with a south-eastern aspect, in the South of England? Di.

199. VEITCH'S SEEDLING PINE-APPLE.—Can you or any of your readers give me information concerning this Pine-apple, of which I have read in some of the gardening papers that it is a most useful variety for autumn and early winter use, second only to the Smooth Cayenne, while it is as free to increase as the Queen. The leaves are said to be tinged with dark red at the margin, and the fruit to be pyramidal, with broad flat dark yellow pips, tinged with red. G. M.

200. RECLAMATION OF LANO.—Some four years ago the sea overflowed one of my fields, and I have since been unable to cultivate anything on it with success. I shall feel greatly obliged if you or some of your practical readers will kindly offer suggestions as to the means of treating the soil. Agricola.

BLACK APHIS ON PEACH TREES—These are, as you say, a fearful pest. There is no remedy so successful as fumigation. Fumigate—fumigate. It is almost impossible to destroy them by any washing or dressing, one is sure to escape somehow, and they breed so rapidly.

BOOKS ON ROSES: Lieutenant. *The Rose Garden*, by William Paul (Kent & Co.); *A Book About Roses*, by the Rev. Canon Hole (Blackwood & Co.); Mr. Cranston's *Cultural Directions for the Rose*; Mr. Rivers' *Rose Amateur's Guide* (Longman), and Mr. Hibberd's *Amateur's Rose Book* (Groombridge). We cannot quote the prices.

EXHIBITING PELARGONIUMS: Bull & Co. and F. Perkins. Rule 17 decides the question. Though your schedule does not expressly stipulate that single plants should be shown, it is always understood that exhibition specimens such as these should not be "made up" plants. This is the rule of the Royal Horticultural Society as referred to in the rule above named, and also of common sense; and therefore we are of opinion that the compound plants were properly disqualified.

HOUSE PLANTS: *Green Leaves.* The Indiarubber, Ficus elastica, the Indian Fan-Palm, Latania borbonica, Aralia Sieboldi or japonica, and the variegated form of Aspidistra lurida. The Aralia is probably the plant you cannot remember the name of.

INSECTS: C. W. S. I. The spotted weevil is a new species believed to be from Ecuador, which was unknown until two or three months ago, when two specimens were taken by Mr. Forbes, in his Orchid-house, feeding on Orchids, and it was then described by Mr. Pascoe, in the *Transactions of the Entomological Society of London, 1877*, under the name of *Cholus Forbesii*. Although found on a Dendrobe that does not at all imply that it is a native of India. The genus *Cholus* is a well-known South American form, confined to that continent. 2. The two caterpillars are the common surface grubs of the garden—larvæ of the Cabbage moth—*Mamestra brassicae*.

NAMES OF PLANTS: T. R. 1, *Pyrus nivalis*, Austria; 2, *Shepherdia canadensis*, Canada.—F. Lloyd, 1, the Maidenhair tree, *Salisburya adiantifolia*; 2, the cut-leaved Alder.—*Philadelphus*. *Philadelphus latifolius*.—C. R. 1 and 2, garden varieties of *Chrysanthemum frutescens*.—*William Gray*, 1, *Dictamnus fraxinella*; 2, *Hemero-callis minor gramineum*; 3,

Eranthemum Cooperi.—J. G. W. *Moltkia petraea*.—G. Marshall, 1, *Valeriana Phu*; 2, *Dicentra formosa*; 3, *Polemonium coeruleum* var.; 4, *Clarkia pulchella flore-pleno*; 5, *Helianthemum mutabile*; 6, *H. apenninum*.—A. G. G. *Magnolia acuminata*.—L. Hurlley, 1, next week; 2, send fresh specimens and leaves of both.—T. Wilkinson. The *Bougainvilleas* both belong to the same species. It agrees very well with specimens collected by Tweedie in South Brazil, having the same small subglabrous leaves. There is also a specimen of it named *B. braziliensis*, but *Chiosy* sinks this under *B. spectabilis*. It seems to be intermediate between typical *B. spectabilis* and *B. glabra*.—C. Harris. *Bromus racemosus*.—Johnson. *Verbascum nigrum*.—A. O. Walker *Humata* (or *Davallia*) *Tyermanni*.

PITCHER ON CABBAGE-LEAF: L. & S. Not very rare. It has been frequently mentioned in the *Chronicle*.

ROSE PETALS: A. S. *Gravesend*.—Well dry the petals in a warm, well-ventilated room, not exposed to the sun, and subsequently turn them out of the jar occasionally.

SEEDLING PANSIES. T. Kettle. The white and yellow varieties are very poor. The others are pretty, but not novel in colour, of fair form, but deficient in size.

STERILE STRAWBERRIES: H. S. No! We cannot explain why your Strawberries have not set their fruit. Had frost anything to do with it? We have also seen the flowers scorched by the bright sun.

STRAWBERRIES: J. Wilson. We do not recognise them in the damaged condition in which they reached us. Ripe Strawberries are not fit subjects to send through the post to name.

VINES: W. R. R. The berries are not diseased, but what is generally termed "scalded"—an injury due to the action of bright sunlight on them while they have been bathed in dew. To prevent this give a little air earlier in the morning, so as to dry up any atmospheric moisture before the sun gets too powerful.

YAM: E. W. If you mean *Dioscorea batatas*, it may be cut into pieces and planted the same time as Potatoes, or a little earlier.

COMMUNICATIONS RECEIVED.—W. Swan (very curious; we will examine and report. Meanwhile, if another specimen appears, please send it in a tin box. The specimen sent was smashed and withered).—C. P.—A. P.—An Old Auctioneer (please oblige us with your name and address).—W. B. S.—C. H. (thanks).—J. D.—J. M. Bagshot.—W. E.—H. (under consideration).—A. D.—T. B.—J. G. & Co.—W. B. H.—An Old Orchid Grower (please send us your name and address).

Markets.

COVENT GARDEN, July 26.

The supply of fruit now reaching us is very much in excess of what was anticipated, and, all things considered, prices have been good. Raspberries and black Currants are in demand, but Cherries sell badly in consequence of the bad state they arrive in. All hot-house fruits have experienced a fall. James Webber, Wholesale Apple Market.

SEEDS.

LONDON: July 25.—Increased animation now characterises the trade for farm seeds. For Trefoils especially there is a good speculative inquiry; and for such parcels as have changed hands an advance of £2 to £3 per ton has been realised. As regards white Clovers there is also a firmer feeling. Of red Clover seed the English crop will not, it is said, be large. The arrivals of home-grown Trifolium are every week becoming more numerous. With a feeble demand and a large supply close at hand prices naturally keep at a low level. No imports of this article from France are yet reported; indeed, this season, both as respects time and also quality, the French are behind the English—at any rate, so far as the London market is concerned. A few choice samples of fine black sowing Rape seed have come to hand, which have been readily placed at rates fairly remunerative to the grower. So soon as the threshing of this description becomes more general, quotations will, it is believed, recede considerably. There is a good sale for field Mustard seed. Canary seed continues quite a dead letter. Blue Peas, in sympathy with the late improvement in the corn trade, are hardening in value. *John Shaw & Sons, Seed Merchants, 37, Mark Lane, London, E.C.*

CORN.

At Mark Lane on Monday trade was decidedly firm. Wheat may be quoted 1s. per qr. dearer than on Monday se'night. Barley moved off quietly at an advance of 1s. per quarter as compared with the prices of this day week. Malt was without appreciable change. Oats were the turn dearer, and in the value of Maize an improvement of 1s. on the week may be reported. Beans and Peas were held for full prices, while as regards flour there was a limited trade doing on last week's terms.—On Wednesday the amount of business done, either separately as respects the various articles or as a whole, was the reverse of encouraging to factors. The market, however, partook of the same firmness of tone, and Wheat, Barley, and other descriptions of produce may be quoted fully as dear as on Monday.—Average prices of corn for the week ending July 27:—Wheat, 63s.; Barley, 32s. 5d.; Oats, 28s. For the corresponding week last year:—Wheat, 48s. 2d.; Barley, 30s. 11d.; Oats, 28s. 5d.

CATTLE.

At Copenhagen Fields on Monday trade in beasts was dull, owing greatly to the restrictions again issued as to the removal of cattle, and prices on the average were unaltered. The supply of sheep was small. Trade was active for them at advanced rates. Choice lambs and calves were in demand, at a slight advance. Quotations:—Beasts, 4s. 6d. to 5s. 2d., and 5s. 8d. to 6s. 2d.; calves, 5s. to 6s. 4d.; sheep, 5s. 4d. to 5s. 8d., and 6s. to 7s.; lambs, 7s. to 8s.; pigs, 4s. 4d. to 5s. 4d.—Thursday's market generally was quiet. Supplies of beasts were rather large for a Thursday. The demand was quiet, at barely Monday's prices. Sheep were steady, but with only a moderate inquiry. Lambs ruled firm. Calves and pigs sold at about late rates.

HAY.

At Whitechapel on Tuesday good fodder is in demand at full prices, but the trade was dull for inferior sorts. Prime Clover, 100s. to 140s.; inferior, 85s. to 95s.; prime meadow hay, 90s. to 124s.; inferior, 70s. to 85s.; and straw, 44s. to 60s. per load.—The supply of fodder on Thursday was large, the trade for which was dull, and prices for new and inferior sorts were lower. Quotations:—Clover, best, 100s. to 140s.; inferior, 85s. to 95s.; hay, best, 90s. to 124s.; inferior, 70s. to 85s.; and straw, 44s. to 60s. per load.—Cumberland Market quotations:—Superior old meadow hay, 130s. to 135s.; inferior, 90s. to 108s.; new hay, 84s. to 108s.; superior old Clover, 132s. to 140s.; inferior, 110s. to 120s.; new Clover, 88s. to 108s.; and straw, 58s. to 63s. per load.

POTATOS.

The Borough and Spitalfields reports state that the supplies continue moderate, and for all descriptions trade remains steady. Kent Regents, 240s.; Essex Regents, 220s.; Kent shaws, 150s. to 160s.; Essex shaws, 150s. to 170s.; Jersey round, 130s. to 150s.; Jersey kidneys, 200s. to 220s.; Cherbourg round, 120s. to 140s.; Cherbourg kidneys, 180s. to 200s. per ton.—The imports into London last week comprised 546 baskets from Rotterdam, 294 barrels 273 baskets 144 casks Dunkirk, 289 barrels 132 casks Hamburg, 635 casks Cherbourg, 313 St. Vaast, 467 baskets 200 hampers Antwerp, 114 packages Boulogne, 112 St. Nazaire, 31 Lisbon, and 25 bags Barfleur.

COALS.

There was a good demand for house coals at market on Wednesday. "Best" realised former prices, while "seconds" advanced 3d. per ton. Quotations:—Walls End—Hetton, 19s.; Hetton Lyons, 17s. 3d.; Hawthorns, 17s. 3d.; Lambton, 18s. 6d.; South Hetton, 19s.; East Hartlepool, 18s. 9d.

THOMAS'S NEW POULTRY FENCING, No. 508.

Very strong and durable. Reduced Prices, 1877.

For Sale, a

STEVENS' IMPROVED TRENTHAM SWROUGHT IRON HORTICULTURAL BOILER, 6 feet long by 3 feet diameter, fitted with Inlet and two Outlet Pipes, Fire-door and Grate complete. For price and particulars apply to HILL AND SMITH, Brierley Hill Ironworks, Dudley.

Silver Medal, 1874. THE TERMINAL SADDLE BOILER.—First-class Certificate, 1867; Highly Commended, 1873; and First-class Certificate, 1875.

"This Boiler possesses the rare merit of sucking all the heat from the fire."—*Gardener's Magazine*, p. 25. "I have no doubt the Best Boiler, that will burn any kind of fuel, is the Terminal Saddle."—*Journal of Horticulture*, p. 327. "For moderate cost and real efficiency the Terminal Saddle is one of the very best."—*The Gardener*, p. 95.

Prospectus post free. T. JONES, Temple Street, Manchester.

STEVENS' TRENTHAM GREENHOUSE BOILER,

After long experience, has proved the most SIMPLE, ECONOMICAL, EFFECTUAL, and LASTING BOILER extant; recently improved. For Illustrations, with full particulars, apply to the Sole Makers,

F. & J. SILVESTER,

HOT-WATER ENGINEERS, &c., &c. Castle Hill Works, Newcastle, Staffordshire. Our Boilers are the ONLY ones made with the sanction and under the inspection of the inventor, Mr. Stevens—all others being base imitations.

JONES'S PATENT "DOUBLE L" SADDLE BOILER.

These Boilers possess all the advantages of the old Saddle Boiler, with the following improvements—viz., the water-space at back and over top of saddle increases the heating surface to such an extent that a "PATENT DOUBLE L SADDLE BOILER" will do about twice the amount of work with the same quantity of fuel; the cost of setting is also considerably reduced, and likewise the space occupied; at the same time these Boilers are simple in construction, and being made of wrought iron are not liable to crack. They are made of the following sizes:—

Sizes.			To heat of 4-in. Pipe.	Price.
High.	Wide.	Long.	Feet.	£ s. d.
20 in.	18 "	18 "	300	7 0 0
20 "	18 "	24 "	400	8 0 0
20 "	18 "	30 "	500	9 0 0
24 "	24 "	24 "	700	12 0 0
24 "	24 "	30 "	850	14 0 0
24 "	24 "	36 "	1,000	16 0 0
24 "	24 "	42 "	1,400	20 0 0
28 "	28 "	60 "	1,800	25 0 0

Larger sizes if required.

From Mr. CHARLES YOUNG, Nurseries, Balham Hill, S.W., May 28, 1873.

"Having given your Patent 'Double L' Boilers a fair trial at my Nurseries, I beg to say that they are most satisfactory. I consider them the best in use, and without doubt the most economical of all boilers; they will burn the refuse of other tubular boilers I have in work."

PRICE LISTS OF HOT-WATER PIPES and CONNECTIONS, with Boilers, of all sizes and shapes; or ESTIMATES for HOT-WATER APPARATUS, erected complete, will be sent on application.

J. JONES AND SONS, Iron Merchants, 6, Bankside, Southwark, London, S.E. When ordering Boilers please refer to the above advertisement.

Rosher's Garden Edging Tiles.

THE ABOVE and many other PATTERNS are made in materials of great durability. The plainer sorts are specially suited for **KITCHEN GARDENS**, as they harbour no Slugs or Insects, take up little room, and, once put down, incur no further labour or expense, as do "grown" Edgings, consequently being much cheaper.
GARDEN VASES, FOUNTAINS, &c., in Artificial Stone, very durable and of superior finish, and in great variety of design.
F. ROSHER AND CO., Manufacturers, Upper Ground Street, Blackfriars, S.E.; King's Road, Chelsea, S.W.; Kingsland Road, E.
 Agents for **LOOKER'S PATENT "ACME FRAMES,"** PLANT COVERS and PROPAGATING BOXES; also for **FOXLEY'S PATENT BEADED GARDEN WALL BRICKS.**
 Illustrated Price Lists free by Post. The Trade supplied.

ORNAMENTAL PAVING TILES, for Conservatories, Halls, Corridors, Balconies, &c., from 3s. per square yard upwards. Pattern Sheets, of plain or more elaborate designs, with prices, sent for selection.
WHITE GLAZED TILES, for Lining Walls of Dairies, Larders, Kitchen Ranges, Baths, &c. Grooved and other Stable Fixing of great durability. Wall Copings, Drain Pipes and Tiles of all kinds. Roofing Tiles in great variety, Slates, Cement, &c.
F. ROSHER AND CO., Brick and Tile Merchants.
 See addresses above.
SILVER SAND, fine or coarse grain as desired. Prices by Post per Ton or Truck-load, on Wharf in London, or delivered direct from Pits to any Railway Station. Samples of Sand free by post.

Oil Paint No Longer Necessary.

HILL AND SMITH'S BLACK

VARNISH for Preserving Ironwork, Wood, or Stone. This Varnish is an excellent substitute for oil paint on all outdoor work, while it is fully two-thirds cheaper. It was introduced upwards of thirty years ago by the advertisers, and its genuine good quality, notwithstanding a host of unprincipled imitators, is fully attested by its constantly increasing sale. It may be applied by an ordinary labourer, requires no mixing or thinning, and is used cold. It is used in the grounds at Windsor Castle, Kew Gardens, and at the seats of many hundreds of the Nobility and Gentry, from whom the most flattering testimonials have been received, which HILL & SMITH will forward on application.

Sold in casks of about 30 gallons each, at 1s. 6d. per gallon, at the Manufactory, or 1s. 8d. per gallon carriage paid to any Station in the Kingdom.

UNSOLICITED TESTIMONIAL RECEIVED MAY 3, 1877.
"The Ryleys, Alderly Edge, Manchester.—Messrs. Hill & Smith.—Sirs,—For some 20 years I have used your 'Black Varnish,' and shall be glad if you will forward me another cask, as I consider it the best thing known for the preservation of all outdoor work, either wood or iron, that requires to be painted.
—Yours respectfully, ALFRED LOWE, J.P."

Apply to HILL and SMITH, Brierley Hill Ironworks, near Dudley; and 178, Queen Victoria Street, London, E.C., from whom only it can be obtained.

CAUTION.—It having lately come to the knowledge of HILL & SMITH that spurious imitations of this Varnish are being offered by unprincipled dealers at a slight reduction in price, they would especially draw attention to the fact that every cask of their Varnish is legibly marked with their name and address, without which none is genuine.

AGRICULTURAL LOCOMOTIVES,

STEAM PLOUGHING MACHINERY,
ROAD LOCOMOTIVES, TRAMWAY LOCOMOTIVES,
STEAM ROAD ROLLERS.

For Prices, Description, and Reports of Working, apply to the Manufacturers,

AVELING & PORTER,

ROCHESTER, KENT; 73, CANNON ST., LONDON, E.C.; and 9, AVENUE MONTAIGNE, PARIS.

AVELING & PORTER'S ENGINES have gained the highest Prizes at every important International Exhibition. The two Medals for Progress and Merit were awarded them at Vienna for their STEAM ROLLERS and ROAD LOCOMOTIVES; and at the last trials of the Royal Agricultural Society of England their AGRICULTURAL LOCOMOTIVES gained the First Prize after exhaustive trials, when one of their 20-horse power Engines, fitted with single slide and ordinary link-motion, indicated 35-horse power, with a consumption of three and one-fifth pounds of coal per horse-power per hour.

Farms, Estates, Residences.

Any one desirous of Renting a Farm or Residence, or Purchasing an Estate, can have copies of the MIDLAND COUNTIES HERALD supplied free for six weeks on stating the purpose for which the paper is required, forwarding name and address, and six halfpenny stamps for postage, addressed, "Midland Counties Herald Office, Birmingham." The Midland Counties Herald always contains large numbers of advertisements relating to Farms, Estates, and Residences for Sale and to be Let.

Eighteenth Edition. By THOMAS RIVERS, 3s. 6d., post-free, from Messrs. THOMAS RIVERS and SON, Sawbridgeworth, Herts; and Messrs. EDMONDSON BROS., 20, Dame Street, Dublin, Ireland. Sold also by Messrs. LONGMAN and CO., Paternoster Row, London, E.C.

ADVERTISERS are requested to note that although we do not object to receive Letters to be called for, we cannot undertake to forward them.

PARTNERSHIP.—A Nurseryman, carrying

on a successful business within 25 miles of London, is desirous of meeting with a Partner. Failing health causes Advertiser to wish to find a man, or men who in, say, one or two years would be able to take over from him the entire business. Money would be required, but every facility be afforded provided substantial guarantees were given. The fullest references given and required.—Address, by letter, giving outline of means and position, NURSEYMAN, Messrs. Norris, Allens & Carter, Solicitors, 20, Bedford Row, London, W.C.

WANTED, a HEAD WORKING GAR-

DENER, where two others are kept; he must understand thoroughly the Management of Vines and Forcing Fruit. To live at lodge, and WIFE to open gate. Wages, 30s. a week.—Apply, by letter, Mr. C., 38, Wigmore Street, W.

WANTED, a HEAD WORKING GAR-

DENER, where two are kept. Married, without family. Must understand his duties—both Vines, Houses, Forcing, and Kitchen Gardening. Unexceptionable character, State age, services, wages, &c.—R. L. L., Esq., Sandridge Park, near Melksham, Wilts.

WANTED, a thoroughly efficient SINGLE-

HANDED GARDENER, well experienced in Greenhouse work, and the Growing of Plants for Cut Blooms, also the general routine of Gardening.—Address, stating wages, references, G. CORNELL, Florist, Colleshill, near Birmingham.

WANTED, a good WORKING GAR-

DENER, who well understands his business, for a place a few miles from London. Two men and a boy kept besides. Married, without family preferred. Wages 25s. per week, with small cottage. Good character required from last situation.—Apply, by letter only, stating ability, age, and all particulars, to W., 25, Old Bond Street, Piccadilly, London, W.

WANTED, at the Royal Masonic Institu-

tion for Girls, St. John's Hill, Battersea Rise, S.W., a MAN and WIFE, without children, the Man to act as GARDENER and to make himself generally useful, the Wife also to make herself useful. Age not to exceed 35. Joint wages £40 per annum, board, lodging, fuel and light provided. Both Man and Wife to apply, in the first place, at the Institution, St. John's Hill, S.W., any day between 10 a.m. and 6 p.m., and afterwards, with Testimonials, at the Office, No. 5, Freamson's Hall, Great Queen Street, London, W.C., on Thursday, August 2, at 4 o'clock punctually.—J. A. RUCKER, Chairman H.C.; R. WENTWORTH LITTLE, Secretary.

TO GARDENERS.—The post of Gardener

to Edwardes Square, Kensington, is vacant. Applicants are invited to address Mr. ALFRED JAMES SHEPHEARD, 1, King Street, Kensington, W., before Thursday, August 3, stating salary required, and two last situations. The Gardener will have the use of the lodge in the Square.

Outdoor Foreman.

WANTED, an active, intelligent, sober, single MAN, well up in the Culture and Propagation of Ornamental Trees, shrubs, Rhododendrons, Roses, &c.—R. P. KER AND SON, Aighburth Nursery, Grassendale, Liverpool.

Propagator of Roses, Rhododendrons, &c.

PAUL AND SON want a clever, experienced Man, as Propagator (Indoors) of Roses, General Hardy Stuff, and Soft-wooded Plants. Efficient help and every encouragement given to a really painstaking Man.—Apply, by letter, to The Old Nurseries, Chesham, N.

WANTED, an IMPROVER, for the outside

in the first place, and afterwards under Glass. One who has had some experience preferred. A first-rate opening. Premium required.—Apply, by letter, to FRANCIS & ARTHUR DICKSON & SONS, The "Upton" Nurseries, Chester.

WANTED, as SHOPMAN and occasional

TRAVELLER, a thoroughly experienced, energetic Man; married. Unexceptionable references required as to ability, &c.—Apply, stating age, salary required, and all other particulars, to X. V. Z., Messrs. Hurst & Son, 6, Leadenhall Street, London, E.C.

Seed Trade.

EDWARD WEBB AND SONS have vacancies for Two experienced young Men, as ASSISTANTS in the VEGETABLE SEED DEPARTMENT.—Address, with full particulars, Royal Seed Establishment, Wordsley, Stourbridge.

Seed Trade.
WANTED, a SECOND SHOPMAN; married; must be industrious, energetic, well up to the trade, and of good address.—Apply, with all particulars, to **ALPHA**, Messrs. Hurst & Son, 6, Leadenhall Street, E.C.

WANTED, a BOOK-KEEPER and CORRESPONDENT. Must understand the Seed Trade and be Correct at Figures.—Apply, stating age, salary expected, and particulars of former situations, to **B. L. PIERPOINT AND CO.**, Seedsman, Horse Market, Warrington.

Seed Trade.
WANTED, an intelligent, respectable young MAN, with some experience, in a small Retail Shop, and to make out Invoices, &c.—State age, reference, and wages, to **JAMES BIRD**, Nurseryman, Downham.

WANT PLACES.

B. S. WILLIAMS, having at the present time several very excellent **GARDENERS** upon his Register, is desirous of placing them in Situations where great experience and trust are required. **B. S. W.** would at the same time beg to intimate that when a Gardener is applied for that the filling of the situation should be left with him, as that would prevent unnecessary correspondence and delay.—Victoria and Paradise Nurseries, Upper Holloway, London, N.

Head Gardeners.
JOHN LAING AND CO. can at present recommend with every confidence several energetic and practical Men, of tested ability and first-rate character. Ladies and Gentlemen in WANT of **GARDENERS** and **BAILIFFS**, or **GARDENERS** for First-rate Establishments or Single-hand Situations, can be suited, and have full particulars by applying at Stanstead Park and Rutland Park Nurseries, Forest Hill, London, S.E.

E. G. HENDERSON AND SON have many excellent **GARDENERS** with approved testimonials for ability now waiting in their Nurseries for re-engagement.

E. G. H. & Son will be pleased to answer any enquiries from Noblemen and Gentlemen requiring such.—Pine-apple Nursery, Maida Vale, London, W.

GARDENER (HEAD),—Age 36, married, two children; thorough practical experience in all branches of the profession. Four years' character.—**T. WOOD**, Ansty Manor, Alton, Hants.

GARDENER (HEAD), where one or more are kept.—Age 30, married, no family; twelve years' experience. Good references.—**Y. Z.**, The Pages, Bexhill, Sussex.

GARDENER (HEAD),—Age 31, married, no family; thorough practical knowledge of the profession in all its branches. Excellent character.—**A.**, Messrs. Jackson & Son, Nurserymen, Kingston, Surrey.

To Nurserymen and Others.
GARDENER (HEAD), age 32,—£10 will be given to any one procuring Advertiser a good situation as above. Eighteen years' experience. First-class testimonials.—**VERITAS**, 2, Westmoreland Street, Portland Place, W.

GARDENER (HEAD), married, without family.—**W. HINDS**, Gardener to Sir Thomas Edwards-Moss, Bart., Otterspool, near Liverpool, will be pleased to recommend as above, a man of undoubted ability and thoroughly energetic habits.

GARDENER (HEAD),—Age 30, single; thoroughly understands the Management of Stove and Greenhouse Plants, Melons, Cucumbers, and Flower and Kitchen Gardening. Good character.—**G. D.**, 27, Rokeby Road, New Cross, Deptford, Kent.

GARDENER (HEAD), to any Lady or Gentleman,—Age 31, married; thoroughly competent in all branches of the profession; fifteen years' practical experience. Five years in last situation.—**X. V.**, 85, Palace Road, New Bromley, Kent.

GARDENER (HEAD),—GEO. FAIRBAIRN, Gardener to the Marquis of Waterford, will have much pleasure in recommending his Foreman to any Lady or Gentleman requiring a really good man. No Single-handed place accepted. Full particulars on application.—Curraghmore Gardens, Portlaw, Waterford, Ireland.

GARDENER (HEAD),—Age 39, married, without encumbrance; thoroughly understands the profession in all its branches. Wife can attend to House during absence of family. Leaving his present employment owing to the breaking up of the establishment. Can have unexceptionable character for last three and a half years. Suburbs of London preferred.—**J. C.**, Guisnes Court, Kelvedon, Essex.

GARDENER (HEAD), age 41, married.—A GENTLEMAN wishes to recommend his Head Gardener to any Lady or Gentleman requiring a really useful and practical man; he has had under his charge for three years a considerable quantity of Glass, large Garden, Pleasure Grounds, Park, Plantations, &c.; he is also sober and trustworthy.—**M. P.**, Post-office, Halstead, Essex.

GARDENER (HEAD),—Age 40, married; Scotch; understands the Early and Late Forcing of Fruits, Flowers, and Vegetables, and the thorough Management of a Nobleman's or Gentleman's place; upwards of twenty years' practice in Noblemen's and Gentlemen's situations in the United Kingdom. Good recommendations.—**R.**, 12, Devonshire Street, West Kensington, W.

GARDENER (HEAD), age 38, married.—**W. ROE** is now at liberty to engage with any Lady or Gentleman requiring a thorough practical man; has had the entire Charge of the Gardens which belonged to the late Mrs. Sumpter, Manor House, Histon, for eleven years, and is now leaving on account of the death of his late employer, and the estate being shut up; thorough knowledge of the Management of a large Garden, Early and Late Forcing, &c. Can forward good testimonials if required.—**W. ROE**, The Gardens, Manor House, Histon, near Cambridge.

GARDENER (HEAD, WORKING),—Middle-aged, no encumbrance; thoroughly understands the profession. Three years' good character.—**A. Z.**, 3, Golder's Hill Terrace, North End, Hampstead Heath, N.W.

GARDENER (HEAD, WORKING),—Age 33, married; understands Stoves, Greenhouses, Kitchen Garden, Pleasure Grounds, Vines, Cucumbers, &c. Good character.—State wages, assistance, &c., to **C. M.**, 9, Zennor Road, Balham, S.W.

GARDENER (HEAD, WORKING),—Well acquainted with Fruit Culture, Stove and Greenhouse Plants, and the general routine of a Gentleman's Garden.—Good character from last situation.—**A. B.**, Messrs. Cutbush & Sons, Barnet Nurseries, Herts.

GARDENER (HEAD, WORKING),—Age 32, married, no family; thoroughly understands the profession. Satisfactory references. No single-handed place accepted.—**A. B.**, 3, Alfred Road, Harrow Road, Paddington, London, W.

GARDENER (HEAD, WORKING),—Age 35, married, one child (age 5); understands Forcing, Flower and Kitchen Gardening, Land and Stock if required. Five years' good character from present employer.—**J. GRIGGS**, The Gardens, Highlands, Mereworth, near Maidstone, Kent.

To Noblemen and Gentlemen.

GARDENER (HEAD), or GARDENER and FORESTER,—Age 40, married; of varied experience in all kinds of Gardening on a large scale in one of the principal places in England. Seventeen years in last situation. Highest references from last employer.—**A. B.**, Eastington, Cirencester.

GARDENER (HEAD, or good SINGLE-HANDED),—Age 32, married, no family. Wife can Manage Dairy or Poultry if required. Good character.—**T. H.**, Colham Green, Hillingdon, Middlessex.

GARDENER,—JOHN COWAN, The Vineyard, Garston, near Liverpool, would be glad to recommend to any Nobleman or Gentleman requiring a first-class Gardener a Man in the prime of life, who thoroughly understands the profession in all its branches, having had many years' experience in some of the best places in England and Scotland.

GARDENER (good SINGLE-HANDED, or where two or three are kept),—Age 30, married; fifteen years' experience as Head Gardener. Good references.—**C. T.**, Berchill Terrace, St. Margaret Road, Hanwell.

GARDENER (SINGLE-HANDED),—Middle-aged; Wife to assist in the Kitchen if required.—**J. N.**, 1, Hooper Street, Hornsey Road, Upper Holloway, London, N.

GARDENER (SINGLE-HANDED, or SECOND),—Age 38, married, two children; twenty years' experience in above; understands Cows and Land. Four years' character.—**C. SEARLE**, Water End, North Mims, Hatfield, Herts.

GARDENER (SECOND, or SINGLE-HANDED),—Age 28, married, no family; understands Forcing Grapes, Cucumbers, Melons, and Flower and Kitchen Gardening. Good character.—**S. H.**, New Town, Durham, Essex.

GARDENER (SECOND), where three or four are kept.—Total abstainer. Nearly two years' good character.—**J. B.**, Rose Cottage, Guestling Hill, Sussex.

GARDENER (SECOND), in a Private Establishment,—Age 23; 6 years' practical experience in the profession. Excellent testimonials from present and previous employers.—Qualifications, &c., from **A. B.**, 11, Holland Street, High Street, Kensington, London, W.

GARDENER (UNDER, or SINGLE-HANDED),—Age 23, single. Can have good reference. Please state wages.—**A. SONGHURST**, Doods Road, Reigate, Surrey.

GARDENER (UNDER),—Age 18. Country not objected to.—Apply, stating wages given, to **J. S.**, 11, Queen's Road, Norland Square, Notting Hill, London, W.

GARDENER (UNDER),—Age 19. Three years' good character.—**W. LISNEY**, Great Bookham, Leatherhead, Surrey.

GARDENER (UNDER), in a Gentleman's Establishment, Houses preferred.—Age 23. Good character. Please state wages.—**C. H.**, 1, Crouch End Hill, Hornsey, London, N.

GARDENER and FORESTER,—WILLIAM HARRISON, Gardener and Forester about seven years to Sir Richard Brooke, Bart., Norton Priory, Kuncorn, Cheshire, is now leaving as soon as he can meet with a similar or separate situation; has served about twenty-two years in some of the best Noblemen's places in England, Ireland, and Wales, and has taken many Prizes for Fruit, Stove and Greenhouse Plants of the best shows; has had the Management of a large Staff of Men in Woods and Garden. Leaving through the unhealthiness of the district, caused by the chemical vapours, &c. The above Nobleman will be pleased to recommend him to any one requiring the services of a thorough practical man in every branch of the profession.—Apply to the above address.

FOREMAN, in a Nobleman's or Gentleman's Establishment,—Age 24; good experience. First-class references.—**G. T.**, The Gardeners, Well Vale, Alford, Lincolnshire.

FOREMAN, in a Nobleman's or Gentleman's Establishment,—Age 21. Good experience. First-class references.—**J. W.**, The Gardens, Highfield Hall, Leek, Staffordshire.

To Noblemen and Gentlemen.

PAINTER, GLAZIER, and GENERAL HAND on an Estate,—Thoroughly handy and useful. Good references.—**E. J.**, Mr. Draper, Head Gardener, Littleworth, Esher, Surrey.

KINAHAN'S LL WHISKY. Universally recommended by the Medical Profession. A pure old spirit, mild, mellow, delicious, and most wholesome. Dr. Hassall says, "The samples were soft and mellow to the taste, aromatic and ethereal to the smell. The Whisky must be pronounced to be pure, well-matured, and of very excellent quality."—Wholesale 120, Great Titchfield Street, London, W.

DINNEFORD'S FLUID MAGNESIA.

The best remedy for ACIDITY of the STOMACH, HEARTBURN, HEADACHE, GOUT, and INDIGESTION; and the safest aperient for delicate Constitutions, Ladies, Children, and Infants.

DINNEFORD AND CO., 172, New Bond Street, London, and all Chemists.

ELLIS'S RUTHIN WATERS.

PURE AERATED WATERS.

ELLIS'S RUTHIN WATERS.—Crystall Springs, Soda, Potass, Seltzer, Lemonade, Lithia, and for Gout, Lithia and Potass. Corks branded "R. ELLIS AND SON, RUTHIN," and every Label bears their Trade Mark. Sold everywhere, and Wholesale of **R. ELLIS AND SON**, Ruthin, North Wales. London Agents: **W. BEST AND SONS**, Henrietta Street, Cavendish Square.

HOLLOWAY'S OINTMENT and PILLS.

—Diseases of the Bowels.—A Remedy, which has been tested and proved in a thousand different ways, capable of Eradicating Poisonous Taints from Ulcers and Healing them up, merits a trial of its capacity for extracting the internal Corruptions from the Bowels. On rubbing **HOLLOWAY'S OINTMENT** repeatedly on the Abdomen a Rash appears, and as it thickens the Abvive Irritability subsides. Acting as a derivative, this unguent draws to the surface, Releases the Tender Intestines from all Acrid Matters, and Prevents Inflammation, Dysentery, and Piles, for which blistering was the old-fashioned, though successful treatment, now from its painfulness fallen into disuse, the discovery of this Ointment having proclaimed a remedy possessing equally derivative, yet perfectly painless powers.

Works: CHELMSFORD.

PAXTON'S CALENDAR.

Now Ready, a New and thoroughly Revised Edition of the

COTTAGER'S CALENDAR OF GARDEN OPERATIONS.

ORIGINALLY COMPILED BY THE LATE SIR JOSEPH PAXTON, M.P.

OPINIONS OF THE PRESS.

"It has been carefully revised by an experienced gardener, and the lists of vegetables, fruit, and flowers have been corrected by the substitution of the most approved modern kinds, in place of those which were mentioned in the first edition, and many of which have ceased to be worthy of cultivation. It is a thoroughly sound, practical treatise; but it has been so long before the public, and so deservedly appreciated, that any special commendation of it now is unnecessary."—*Midland Counties Herald*.

"This is a handy volume, consisting of seventy pages of letterpress and illustration, containing much and varied information likely to prove useful to all cottagers, &c., who possess a garden. To all such, who require a cheap and reliable book of reference, we heartily recommend it."—*Lloyd's*.

"We are quite glad to see this useful little book once more, and it is like a whiff of perfume from the heather in bloom to read on the wrapper 'two hundred and twenty-first thousand.' We advise all who are interested in the promotion of cottage gardening to sow this little book broadcast."—*Gardeners' Magazine*.

"The information conveyed in this little book is well adapted for all persons having small plots of ground. The necessary operations for each month are clearly laid down, and are of a thoroughly practical nature. The sorts of loth fruit and vegetables are well selected, many of them being excellent in quality. To our readers who are interested in the cultivation of their flower and kitchen gardens, we can safely recommend this as being a most concise and useful work."—*Bell's Messenger*.

The **TWENTY-SECOND ANNUAL EXHIBITION** will take place at Dane Court, St. Peter's, Thanet, on **WEDNESDAY**, August 29, by kind permission of Latham Tomlin, Esq., in his picturesque grounds. Intending Exhibitors are particularly requested to notify (at least Four clear days before the Day of Show) to the Secretaries the number of articles they intend to exhibit, and, if possible, what space will be required, as the rules of the Society this year will be strictly carried out. Schedules can be forwarded on application to the Secretary, **HENRY AUSTEN**, Jun., Fairfield, St. Peter's. The Exhibition will be opened to the Public and Subscribers at 2 p.m. By kind permission of Captain Commandant Dorman the Band of the 8th Cinque Ports Artillery Volunteers will perform a choice selection of music at the above *etc.*

N.B.—This Annual Exhibition is now open to all England.
CHARLES DOBSON SMITH, Hon. Sec.
Margate, August 1.

THE

IMPROVEMENT OF LANDED ESTATES, By **DRAINAGE, ENCLOSING, CLEARING**, and the **ERECTION OF FARM BUILDINGS AND COTTAGES**.

The **Land, Loan and Enfranchisement Co.**

(Incorporated by Special Act of Parliament)

ADVANCES MONEY.

1st.—To the **OWNERS OF SETTLED AND OTHER ESTATES**, for the Erection of Farm Buildings and Cottages, and for the Drainage, Irrigation, Enclosing, Clearing and General Improvement of Landed Property in any part of the United Kingdom.

2d.—To the **OWNERS OF SETTLED ESTATES** in **ENGLAND**, for the Erection or Completion of Mansions, Stables, and Outbuildings.

3d.—To **LANDOWNERS** generally, to enable them to subscribe for Shares in Companies for the Construction of Railways and Navigable Canals, which will beneficially affect their Estates.

4th.—To **INCUMBENTS**, for the Improvement of their Glebe Lands, by Drainage, and the Erection of Farm Buildings and Cottages.

5th.—To **COPYHOLDERS**, for the Enfranchisement of Copyhold Lands.

The amount borrowed, with the expenses, would be charged on the Estate benefited, and repaid by a rent-charge, terminating in twenty-five years.

No investigation of the Landowner's Title is necessary. Forms of application, and all further particulars may be obtained of

Messrs. **RAWLENCE AND SQUAREY**, 22, Great George Street, Westminster, S.W., and Salisbury; of Messrs. **ASHURST, MORRIS, CRISP, AND CO.**, 6, Old Jewry, London, E.C.; of Messrs. **GILLESPIE AND PATERSON**, W.S., 81a, George Street, Edinburgh, Agents for the Company in Scotland; and at the Offices of the Company, as below.

T. PAIN, Managing Director.

EDWIN GARROD, Secretary.

Land, Loan, and Enfranchisement Company,
22, Great George Street, Westminster, S.W.

Seedlings.

H. CANNELL begs to announce that he has many thousands of **PRIMULAS, CALCEOLARIAS, and CINERARIAS**, at 1s. 6d. per dozen; they are just ready for potting off. All of them are of James' first exhibition varieties. Special prices for large quantities.

HARRISON'S MUSK.—H. Cannell begs to assure the public generally that the above now creates quite a sensation in Covent Garden, in fact there is quite a mania for it; probably a more saleable and profitable plant was never sent out. H. C. will send two plants, post-free, for 1s. 20s. per 100.
Swanley, Kent.

TO THE TRADE ONLY.

COCOS WEDDELLIANA, good plants, 63s. and 84s. per doz.

Address—CRANSTON & CO.

NEW ENGLISH-RAISED SEEDLING ROSES.

MESSRS. BELL & SON, THE NORWICH NURSERIES,

Are now executing orders for their TWO NEW ROSES, raised at their Nurseries, and described and announced below. They have been thoroughly tested here before being sent out, and can be recommended with confidence as really distinct novelties.

CLIMBING ROSE "CATHERINE BELL."

Very large flowers of a deep rose colour, the backs of the petals a delicate silvery pink, of exquisite shape and very fragrant. It is very free-flowering, and of vigorous climbing habit, making shoots 6 feet to 8 feet long in one season. Figured in The Garden, March 18, 1876.

"Your Rose Catherine Bell is both belle et grande."—Rev. Canon Reynolds Hole.

Good Flowering Plants, in Pots, 10s. 6d. each.

COLOURED PLATES ONE SHILLING EACH.

HYBRID TEA ROSE "MRS. OPIE."

Bright salmon-rose, tea-scented flowers, with shell-like petals, a most distinct and novel shade of colour among Tea Roses. It will form a charming companion to Madame Falcot, and will be as extensively cultivated as that variety when well known. In flower from May to November. Figured in the Floral Magazine.

Good Flowering Plants, in Pots 7s. 6d. each.

BELL AND SON, 10 & 11, EXCHANGE STREET, NORWICH.

BY HER MAJESTY'S ROYAL LETTERS PATENT.

WRIGHT'S ENDLESS-FLAME-IMPACT HOT-WATER BOILERS.

Guaranteed the most Powerful, the most Rapid, the most Economical, the Simplest, and the Cheapest in the World.

"The 'Boiler of the Future:' I have no doubt about this."—WM. THOMPSON, Tweed Vineyards.

Our Patent Endless-Flame-Impact Boilers have excited a very great degree of interest, not only in this country, but also in Austria, Germany, Holland, Belgium, France, United States, &c.—from all of which we have had many inquiries. We feel sure the details of the experiences of the first ones put to work will be read with interest:—

"The Gardens, Drumpellier, Coatbridge (N.B.),
December 1, 1876.
"Messrs. WILLIAM WRIGHT & Co.,
Hot-water Engineers, Airdrie (N.B.).
"GENTLEMEN,—The setting of your No. 6 'B' Boiler being so far forward on Wednesday last, I determined to get it started. The Pipes and Boiler being filled with water, a very small fire was lit. The effect on the Pipes was, I may say, instantaneous, as in a few minutes the hand could hardly be held on them, so very hot were they. This was the more remarkable, as bricks, lime, and everything were thoroughly wet, having been deluged by the previous rains whilst standing undisturbed. With other Boilers it generally takes a good many days before the brickwork dries, and they answer to the fire; but the moment the fire was lighted in yours, although all was soaking with damp round about, the heat rushed into the Pipes with a rapidity I have never seen equalled. There can be no question, therefore, as to its great power and extreme rapidity in working. What makes these results the more remarkable is, that we had no chimney—our bricklayer not having had time to get one erected—save a common fire-clay pipe on top of the Boiler, only about 18 inches high. I took this off repeatedly, and the furnace went quite well without it, so that its requirements in the matter of a stalk appear to be very slight indeed. I expect about half the usual quantity of small coal will be quite sufficient for it, as the 'Water Jacket' effectually prevents the loss of heat from any cause whatever, whilst the temperature of the escaping gases was so very low that I repeatedly held my hand in them, as they left the Boiler, without the slightest discomfort. Altogether we are greatly pleased with it, and have no slight doubt, but that it will give the greatest satisfaction. I will hand you the pyrometer readings, for the temperatures in the various sections, very shortly.
"I am, Gentlemen, yours truly,
(Signed) "H. W. LEWIN."

On the 6th inst. he favoured us with the following additional particulars:—

"The Gardens, Drumpellier, Coatbridge (N.B.),
December 6, 1876.
"Messrs. WILLIAM WRIGHT & Co.,
Hot-water Engineers, Airdrie (N.B.).
"GENTLEMEN,—Since writing you on the 1st inst. I have got about 5 or 6 feet of a stalk erected. The draught still continues excellent—in fact is rather in excess. The Boiler is rising in favour with us every day, as we become more and more acquainted with its good qualities. At first I intended firing it with our usual mixture of coal and dross, but found the heat far too high. We therefore put in dross alone, but even with that we have too high a temperature. Last night, to prevent this, we filled up with the dirtiest rubbish we could find, but when trying to 'turning in' for the night, we found Boiler and Pipes and Houses again so hot that we shoved the damper in altogether, or nearly so: left three of the soot-holes open, to reduce the heat in the Boiler, if possible; and a large space open for ventilation in the top of the House. But in spite of all these precautions, the temperature this morning was about 70°. It is certainly a most extraordinary Boiler, and the men are all quite taken up with its performances. I shall use the refuse from the other Boilers and all the rubbish about the place for it, as nothing appears to come amiss to it. In fact, we are forced to try this to keep down the temperature; although, so far as we have attempted this remedy, it does not promise great success, as your Boiler appears to give nearly as much heat from rubbish as many Boilers do from the best coal, whilst the small quantity consumed, as compared with others, is quite remarkable. We are confident, also, that we will get rid of our usual night-work by means of your Boilers, as they seem to be quite capable of keeping up nearly any temperature for many hours without attention. Knowing the generally highly-sanguine temperament of inventors, I certainly was inclined to receive your assertions in your pamphlets and elsewhere as to the great benefits and advantages you had secured in your Patent Endless-Flame-Impact Hot-Water Boilers with a certain amount of reserve, and to allow a considerable margin for miscarriage of one sort or another; but I feel bound to say that, as far as our experience has gone with the Boiler you sent us, its merits have not been overrated by you, but the reverse. I shall have great pleasure in showing it to any one who may wish to inspect it.
"I am, Gentlemen, yours truly,
(Signed) "H. W. LEWIN."

"The Gardens, Parson's Green, Edinburgh,
February 8, 1877.
"Messrs. WILLIAM WRIGHT & Co.,
Hot-water Engineers, Airdrie.
"GENTLEMEN,—In answer to your enquiries regarding your 'No. 4 D' Boiler, fitted up here by Messrs Melkie & Philip, Horticultural Builders and Hot-water Engineers, &c., Edinburgh, I beg to inform you that I am more than satisfied with

its heating powers. Although everything about the Boiler was damp, I found I could heat all the pipes—upwards of 2200 feet of 4-inch pipes, many of them exceeding 4 feet in difference of elevation—in less than an hour, so that you could not bear to hold your hand on them. This result I never could attain with the aid of the two large oval flue Boilers I had before: whilst the consumpt of fuel is less than one-half.
"The draught is excellent (having been obliged to put in a damper) although the flue goes horizontally 79 feet under the wall, with only a rise of 18 feet of vent. One of the good qualities of your Boiler is the ease of its erection. Even with such a large and heavy Boiler as your '4 D' (nearly 20 cwt.), I had no difficulty in passing all the sections through a trap door in stake-hole 2 feet by 4 feet, and setting it up in a recess 4 feet square without the least trouble, and I am confident that, with the help of two men, I could take the whole Boiler down and have it again in full working order in less than two hours. Attached to Boiler are about 250 feet of 4-inch piping for drying-room in Laundry, and to none has your Boiler given greater satisfaction than to those in this department, where heat is an important element. From the careful examination I made of your Boiler at Drumpellier, and from my own experience of its performances here, I thoroughly endorse the statements Mr. Lewin has made regarding its many excellent qualities, and quite agree with him that you have rather underrated them than otherwise. The usual night work and late stoking too has been entirely got rid of, as it can be left from any hour in the evening till next morning without the slightest misgiving, and with little variation of temperature. Not the least of your Boiler's good qualities is its cleanliness, as there is no soot to be pulled out—all goes to flame. I consider the Horticultural World owes you a debt of gratitude for your invaluable invention, and I shall have much pleasure in giving public demonstration of its powers to any one interested in the matter.—I am, yours respectfully,
"JOHN CLARK."

Mr. David Thomson, author of *The Handy-Book of Fruit Culture under Glass*, *Handy-Book of the Flower Garden*, editor of *The Gardener*, and gardener to His Grace the Duke of Buccleuch, at Drumlanrig Castle, has favoured us with a note on the same subject, from which we extract the undernoted:—

"The Gardens, Drumlanrig Castle, Dumfriesshire,
February 22, 1877.
"Messrs. WM. WRIGHT & Co., Airdrie.
"GENTLEMEN,—Although a dabbler in Boilers, I think yours the most perfect 'Heat Trap' yet invented. We are going to put up another new range, and shall put one of your Boilers in, and in the interest of the public shall not lose a chance of recommending it.—Truly yours,
(Signed) "DAVID THOMSON."

We have been kindly favoured with the following from Mr. WILLIAM THOMPSON, of the celebrated Tweed Vineyards, author of the standard work on *The Vine, and its Cultivation*, and late Gr. to His Grace the Duke of Buccleuch, at Dalkeith Palace:—

"Tweed Vineyards, Clovenfords, by Galashiels,
December 15, 1876.
"Messrs. WILLIAM WRIGHT & Co.,
Hot-water Engineers, Airdrie.
"GENTLEMEN,—Thanks many times for your prompt and kind reply to my enquiries about the Boiler. I have studied it as far as your able pamphlet and woodcuts have enabled me, and I have come to the conclusion that it is 'The Boiler of the Future.' I have no doubt about this. . . . I shall use it for the one I need in February, but hope, before then, to run through and see it; and, if it answers, as I hope and believe it will, it may be a question if I should not pull out some of the Boilers I have in use, good as these are, for, if coal can be saved, the price of a Boiler can be made up in a few years. The Boilers I have here doing the heaviest work are of my own design—fire goes from A to F and back under the Boiler, then over the top and up chimney at D, thus traversing 60 feet. The Boiler is all bricked round of course, but the direct upward impact of the fire on yours is far better and more powerful than in them. Still you will see they are powerful Boilers; yet, with your Boiler before me I would not have them repeated if they gave way till I had a trial of yours.—I am yours truly,
(Signed) "WM. THOMPSON."

On February 20, 1877, after inspecting our

"4 D" at Parson's Green, near Edinburgh, he further writes us:—

"Messrs. WILLIAM WRIGHT & Co., Airdrie.
"GENTLEMEN,—When in Edinburgh I went out to Parson's Green, and saw the Boiler at work, and, as I expected to find, nothing could be more satisfactory than the way it does its work. . . . I am yours truly,
(Signed) "WM. THOMPSON."
A few months ago we supplied Mr. Thomson with one of our large Boilers. He is so satisfied with it that he has since ordered five of our largest, and says all his fifteen other Boilers will be discarded and ours alone used, as he feels certain he will get his work better done, and at the same time save at least half of his annual coal bill.—See "The Gardener" for July.

"6, Constitution Terrace, Dundee, March 9, 1877.
"Messrs. WILLIAM WRIGHT & Co., Airdrie.
"DEAR SIRS,—The Boiler recently had from you is very efficient, and promises continued satisfaction in every respect. The consumption of fuel is very small, and no furnace could do with less attention. I will be most happy to show and explain it to any one who may be making inquiries in this quarter.
"I am, dear Sirs, yours truly,
"J. A. STEWART."
"Brewery, Newport, Isle of Wight,
March 7, 1877.

"Messrs. WILLIAM WRIGHT & Co.,
Engineers, Airdrie (N.B.).
"DEAR SIRS,—I am instructed by Mr. William B Mew to forward you the enclosed cheque for amount of account, which kindly acknowledge, and he wishes me to say that the apparatus is fixed and at work, and the result is highly satisfactory, but, owing to the very short time it has been in use, it is impossible for him to speak with certainty as to its durability.
"Yours truly,
(Signed) "W. WEEKS."

"Boston Spa, Yorkshire, March 27, 1877.
"Messrs. WILLIAM WRIGHT & Co., Airdrie.
"GENTLEMEN,—In the latter part of October of last year I requested you to send me one of your pamphlets. I duly received it, and was well pleased with it, and consulted my horticultural friends about your Boiler. Some shook their heads and said it was but an advertising puff; others, too cheap to be good; and not one gave me any encouragement to try it. My answer was, I would chance it, and if it proved only one-half what it was represented to be I should be well satisfied. I ordered one in November last, which came to hand shortly thereafter. It was at once erected and put to work, and I feel bound to say your Boiler is A 1. It does everything you state in your pamphlet, even more. A friend of mine of very great practical experience, a nurseryman (from whom you will shortly receive an order) is about to pull out a Saddle-boiler, not two years put in, to replace it with one of yours. He has seen my fire lighted and Boiler working at all its stages, and says it is marvellous, and pronounces it 'the best Boiler in the world.' As I am in the centre of a large horticultural district, I shall be most happy to show any interested parties your Boiler at work, as I consider it a great boon—it having great heating powers, causing very little trouble, and the consumption of fuel very small compared with other Boilers.
"I am, Gentlemen, yours truly (Signed) R. STUART."

"The Gardens, Preston House, North Shields,
April 2, 1877.
"Messrs. WILLIAM WRIGHT & Co., Airdrie.
"SIRS,—For these last thirty years both brains and temper have been frequently and heavily tried with Boilers, which in their turn were considered the best out. Indeed, there are few of any note but I have had something to do with, but never found one to give anything like satisfaction till we tried yours. We have now got it into thorough working order, and certainly it pleases me beyond what I expected in all respects. I can have it boiling in twenty-five minutes, which I could not do with some of the others in as many hours, and that with very little fuel, the saving from which will in time pay the price of it. With a well-regulated damper I can bank up the fire to keep in a stalk is required, as it will do without one, and will burn almost anything. There is not a question of a doubt but that it will very shortly be 'The Boiler of the Day.' When I first saw it in the *Gardener's Magazine* I told Mr. Fenwick that I preferred it to any I had seen. I am, therefore, the more delighted with the highly satisfactory result. It was put up by the joiner and myself in a very short time.—Your most obedient servant,
(Signed) "JAMES McQUEEN."

For details and particulars as to the various sizes made, and prices, please see our pamphlet, entitled, "Our Boilers and Heating," which will be handed to all applicants, post-free.
We are prepared to supply THIRTY DIFFERENT BOILERS of all powers, sizes, and heights, and can vary these to suit any particular situation or requirement.
BOILERS SPECIALLY DESIGNED FOR LOW AND OTHER INCONVENIENT POSITION.

WM. WRIGHT & CO., HOT-WATER ENGINEERS, AIRDRIE, NEAR GLASGOW, N.B.

BOULTON & PAUL,

HORTICULTURAL BUILDERS,
NORWICH.

No. 75.—MELON FRAMES and FORCING FRAMES.

The largest Stock in the Kingdom, ready to be despatched on receipt of order.

These Frames are made of the best red deal, thoroughly seasoned, and fitted by first-class workmen: 24 in. high at the back, 13 in. high in front; painted three coats of good oil colour, glazed with best 21-oz. glass, every pane of which is nailed in and bedded in with putty—the best method of glazing known, and adopted by the most eminent Builders and leading Nurserymen (See *The Garden* for January 13, 1877, p. 30). Iron handles to each light, and an iron strengthening bar across. Each light is 6 ft. by 4 ft., and 2 in. thick.

CASH PRICES (Carriage paid).

	Length.	Width.	£ s. d.

B. S. WILLIAMS'
NEW AND CHOICE

FLOWER SEEDS FOR 1877.

CALCEOLARIA, Williams' Superb Strain, 5s., 3s. 6d., 2s. 6d., and 1 6

From Capt. COSENS, Aberystwith, May 13, 1877.
"The Calceolarias, from the seed Capt. Cosen had from Mr. Williams last year, have been greatly admired—they leave nothing more to be desired."

PRIMULA, Williams' Superb Strain, Red, White, or Mixed .. 5s., 3s. 6d., 2s. 6d., and 1 6

PRIMULA SINENSIS FIMBRIATA COCCINEA (new), colour brilliant scarlet with bright sulphur eye, exquisitely fringed and of great substance .. 5 0

From Mr. F. DENNING, Gardener to J. Fenton, Esq., Yardsley, February 26, 1877.

"Dear Sir,—I may inform you that at the Birmingham Chrysanthemum Flower Show, held last November, I took the 1st prize, with twelve Primulas, six red and six white, in the Gentlemen's Gardeners' Class, with seeds supplied by you."

CINERARIA, Weatherill's Extra Choice Strain, 5s., 3s. 6d., 2s. 6d., and 1 6

From Mr. J. WEST, Gardener, Chaddon Park, May 21, 1877.

"Sir,—Your strain of Cinerarias, which have now been in bloom some time, have been and are now the admiration of all that have seen them, and are considered by gardeners to be the best ever seen in this neighbourhood. Habit very dwarf and compact, quite equal to the drawing in your catalogue."

CYCLAMEN PERSICUM GIGANTEUM (new) .. 5s., 3s. 6d., 2s. 6d., and 5 0

Do., do., Williams' Superb Strain, 5s., 3s. 6d., 2s. 6d., and 1 6

VICTORIA and PARADISE NURSERIES,
Upper Holloway, London, N.

SATURDAY, AUGUST 4, 1877.

NOTES FROM CHISWICK.

THERE are not a few of the old school of horticulturists who are fond of prating about the "palmy days of Chiswick." Well, no doubt they were "palmy days," for they included a much larger garden, a fine arboretum, a splendid Apple orchard, grand flower shows, and much grander company. If those days have passed away, horticulture is none the worse, for gardening is quadrupled in extent, and the one or two great flower shows of the fashionable suburb have developed into hundreds elsewhere. But if our older friends will regard the great show times of Chiswick as its palmy days, perhaps younger men may be induced to regard its present days as Chiswick's "practical" ones, for there is no other garden in the kingdom where more useful or more practical work is being done, and the Royal Horticultural Society, if it displays a somewhat gaudy bust at South Kensington, finds its backbone in the genuine horticultural work being accomplished farther west.

During the season—we mean, perhaps, the garden season—country cousins of the blue-apron fraternity pay their customary visits to the metropolis to see whatever can be seen in the way of flower shows, nurseries, and specially bedding-out displays—too true is it, alas! that these latter present a more powerful attraction than other garden sights—and to make a point of doing Battersea, Victoria, and Hyde Parks, that they may pick up the latest notions in bedding-out, which on their return they try to imitate, to their entire confusion and regret. The famed fable of the frog and the bull was intended to have a significance for all time, and it certainly has even in such small matters as these. If for once our garden friends can be induced to forego one of their customary floral *picnics de resistance*, and will instead take a look in at Chiswick, they will find much there to please and to instruct, and will probably pick up some crumbs of information not obtainable elsewhere. There is variety, and that is said to be charming, but apart from the variety there is much there that is intrinsically charming also.

Metaphorically we will take our visitors round to see what we saw there a few days since, and if they like the metaphor, certainly they cannot do better than turn the illustration to practical account. To begin with that humble but favourite garden flower, the annual Stock, we find the whole range of beds that on one side border the broad entrance walk, are filled with these, all the known home-grown and Continental varieties being represented. Here is a lot of useful food for digestion, but a farther disquisition on the respective merits of each kind we leave to some future day. In the beds on the grass plat are found arranged in colours all the very best old and new Zonal and "decorative" bedding Pelargoniums of the day. An hour might be spent with these to advantage, to the enlightenment of many provincial raisers of these things, and to the removal of much local conceit. So truly fine are many of these kinds that Denny, Postans, and George will soon find the ideal realised beyond which progress becomes retrogression. Here also are beds of Balsams raised from seed of all the best trade collections in plants, five of a sort, and duplicates of all

are being grown in pots elsewhere. Pentstemons of all the best kinds, Phloxes, and other good border flowers, are also found here in bloom. In the new herbaceous garden are dwarf Campanulas and many novel and other things, and beds of various interesting annuals, and many other interesting things too numerous to mention. Beyond the Pelargoniums, on a shady border to the right, are planted the bedding Violas and Pansies in immense variety, and most charming they are. In all directions are sowings of hardy annuals and biennials—all good, well-rogued stocks, and as the trade usually send seed of their best novelties to Chiswick, not a few good things may be seen there for the first time—the charming new rose-salmon Candytuft, recently alluded to by us, and its compeer, the new dwarf white, growing with all the older kinds; the new elegant Lady Albemarle Godetia, with a dozen other sorts; Clarkias in variety, including the new double kinds—in fact, lots of things that should be seen to be appreciated.

In the houses are many good things that can only be seen at Chiswick. The grand curvilinear vinery is a unique sight, and the Vines well cropped. The orchard-house makes a brave display, and forms one of the most valuable glass erections in the gardens. The long Peach-house, in which the trees are trained in the cordon-oblique style, gives a remarkable collection of that kind of wall fruit. In a lean-to is a very extensive collection of Tomatos in pots, all now fruiting, and close by is a show house, in which there is a charming collection of single and double Pelargoniums. Of the single kinds a superb scarlet of Mr. George's raising, named Lord Mayo, proved to be singularly noticeable for its splendid flowers and capital habit as a pot plant. In another show house there is seen a large collection of the tuberous-rooted Begonias in full bloom, all very beautiful but displaying rather too much of the orange-scarlet hue. There is also in flower a collection of Fuchsias, and lovers of this beautiful pot plant are specially requested to notice Laing's new hybrid out of Fulgens—at least, so it is said to be—Lord Beaconsfield, a capital decorative kind, and, not less attractive, Bland's grand dark double Champion of the World: this is at once a monster and a magnificent variety. On a side shelf are some plants of the best of the Ivy-leaf section of the Pelargonium, a few old bottoms—that is, plants of two years' growth—having developed into very handsome exhibition specimens, some flat and others pyramidal, as the habit of the plant is followed. Here is an idea for the framers of the next schedule of the Pelargonium Society; let them send the wretched golden and bronze Zonals to perdition, and put in a class or two for Ivy-leaves, and, oh, let them be untrained, except by judicious pinching. Further, we may in pity ask the hybridists, if they will raise new kinds, not to attempt to spoil those charming things; they have soft and pleasing hues of colour, have neat but varied foliage, are elegant both in habit and in flower, and as they may but improve only to spoil, we beg of them to leave these to us in all their present elegance and beauty.

Out-of-doors there is seen in a warm south border a remarkable collection of Tomatos, planted three lines deep, all the plants trained flatwise to stakes. Farther on a very extensive trial of garden Turnips, including the various French and Spanish kinds, is full of interest to vegetable cultivators. In another place there is an extensive assortment of Savoy Cabbages, in another rows of numerous sorts of Potatoes, in another Peas and other vegetables. In the fruit quarters are large collections of Gooseberries, Raspberries, Currants, and Strawberries, and on the Nuts and Filberts a marvellous crop of fruit such as will enable the various features of each kind to be correctly studied.

The pyramidal Pears, Plums, Cherries, &c., are splendid trees, with this year, alas! no fruit, but in this sense they are simply exhibiting action in unanimity with similar fruits elsewhere.

These are some, by no means all, of the features to be seen at Chiswick at the present time, but they fairly indicate how much valuable work is being done there—thanks to Mr. Barron's unflagging zeal and consummate generalship. To keep Chiswick going in so creditable a manner as Mr. Barron has done in the face of the enormous difficulties he has had to contend against during the past few years, has been a task of no ordinary dimensions, but it has been done and done well, and the hearty thanks of every horticulturist are his due.

New Garden Plants.

PHÆDRANASSA VIRIDIFLORA, Baker, n. sp.*

This is a new species of *Phædranassa* which flowered this summer with Mr. Elwes at Cirencester. He received it from Holland under the name of *P. obtusa*, from which it differs by its lanceolate leaves, and flower quite destitute of red, with a longer tube and shorter segments. Like the other species it dies down to the root in autumn, is scentless, and the leaves are not fully developed till after the flowers fade.

Bulb ovoid, 1½ inch in diameter, with a tuft of thick fleshy fibres at the base; tunics thin, brown, membranous. Leaves lanceolate, bright green, glabrous, under 1 foot long, 18–21 lines broad at the middle, acute, and narrowed from the middle to a short petiole, which is flat on the face; midrib distinct, chaonelled down the face; veins fine, immersed. Scape a foot long, terete. Spathe of 3–4 membranous linear or lanceolate valves 1–1½ inch long. Umbel 4-flowered; pedicels cernuous, ½–¾ inch long. Ovary obconic-triquetrous, green, ¼ inch long; perianth narrowly funnel-shaped, 1½ inch long; tube greenish-yellow, ¾–1 inch long; segments oblanceolate-spathulate, 1 inch long, green, passing into whitish at the base, the outer ones 3½–4 lines broad, furnished with a distinct cusp at the tip, the inner ones rather broader, without any cusp. Filaments inserted at the throat of the perianth-tube, white, linear, simple, as long as the perianth-segments; anthers versatile, linear-oblong, varying from 2 to 4 lines in length. Style declinate, a little exserted; stigma capitate. ♀. *G. B.*

CELOGYNE MAYERIANA, n. sp.†

For many years I had this as a most doubtful plant in my herbarium, sent from England. The required information had not been given, and I was not sure whether I had before me a starved *C. pandurata* or a new species, or a monster of the first-named. Thus it had to be laid aside in my herbarium, the grave of not a few doubtful plants. Finally it reappeared last winter during the shortest days, when Herr Garten-inspector Mayer of Carlsruhe, the most skillful assistant of his excellent father, Herr Garten-director Mayer, twice sent me inflorescences and plants. I obtained such information that at length I became persuaded this is a totally distinct thing. Reduce a *C. pandurata* to half its size, and you begin to have a pretty good idea of our novelty. The bracts have to be reduced much more. The great difference is found in the lip. Its basilar part is longer than is that of *C. pandurata*, the anterior part is broader, and there is scarcely any middle part (nail, unguis, isthmus) at all in this, but it is well known *C. pandurata* has one that reaches nearly ¼–½ of the whole of the lip. The side lacinia project in sharp acute angles in the old species, while in the new one they are blunt rectangular. The very base of the middle lacinia has some ramentaceous small obtusangled lamellæ, in the new one there are two cushions nearer the centre, consisting of many small lacinia. That elevation of approximate plates on the base of the lip,

* *Phædranassa viridiflora*, Baker, n. sp.—Bulbo ovoides, tunics brunneis membranaceis; foliis lanceolatis acutis viridibus subpedalibus breviter petiolatis; scapo tereti subpedali; spathe valvis membranaceis linearibus vel lanceolatis; umbellis 4 floris; pedicellis cernuis perianthio 2–3-plo brevioribus; perianthii sesquipollicaris tubo anguste infundibulari flavo-vidi limbo duplo breviori, segmentis diu erectis oblanceolatis viridibus inferne albidis; filamentis edentatis linearibus segmentis æquilongis; stigmatè exserto.

† *Ceologyne Mayeriana*, n. sp. Rehb. f.—Aff. *Ceologyne pandurata*, Lindl., subduplo minor; pseudobulbis depresso-pyramiformibus acutibus, diphyllis; foliis petiolatis oblongis acutis, Stanhopearum; pedunculis erectis racemosis plurifloris; bracteis scariosis ligulatis acutis ovaria pedicellata semi-æquantibus habet conspicuis; sepalis ligulatis acutis; tepalis angustioribus; labello trifido, lacinis lateribus basi semi-cordatis, semioblongis, antice obtusangulis, lacinia media ab isthmo brevissimo subnullo hastato semioblongo toto limbo crispulo, carinis plicatis ternis a basi in basi lacinia; antice; tuberculis ex lamellis crispulis ibi geminis; venis radiatis omnibus atratis incrassatis; columna apicem versus ampliata; basi utrinque angulata.—*C. h. Carlsruhe, ab exc. Mayer.*

so conspicuous in the old species, is not to be seen in the new one, where the keels run without those elevations of *C. pandurata*. The colours are identical. The bulbs I saw were narrower and not arched out at the sides. Yet I do not believe in the constancy of those features. I have with great pleasure named the plant *Mayeriana*, in memory of the two highly talented curators of the most remarkable aulic garden of Carlsruhe. *H. G. Rehb. f.*

NOTES ON THE PAST SEASON.

THE entire loss of hardy fruit crops, with but very few exceptions, will ever be remembered by those who are in any way engaged in or connected with fruit growing, either for private or marketing purposes, and what is still worse, the dire effects of the inclement weather have not been confined to outdoor crops alone. Never do I remember to have seen more brilliant prospects of a Pear crop, and its complete annihilation must be a sad contemplation for many like ourselves. The desperate cold winds that prevailed during the spring were bad enough, but it was left to the frost on the night of May 2 to obliterate any ray of hope that one had. We registered 7° of frost on the night of the 2d here, whilst in London it was nearly doubly severe. The Apple orchards were in full blow at the time, so that I fancy the Apple crop will be more abundant all through the northern counties on account of the blossom not being in so advanced a state at the time.

All stone crops out-of-doors are a complete failure, indeed Peach trees have suffered so much that it may be a year or two before they are able to recoup themselves. Plums are in a similar plight, and have suffered severely from the attacks of insects; they, too, will require the most minute vigilance to restore them to a healthy condition. Figs are plentiful out-of-doors here, and never require protection. The aspect, the climate, the natural soil, and its adaptability for growing certain things will account, in a great measure, for the apparent differences of opinion in these matters.

Of small fruits there is a great abundance, especially Strawberries—our former recommendations still hold good with regard to this, the most valuable and esteemed of small dessert fruits. Keens' Seedling, imported from a distance, does well for a season, and then degenerates from a fruitful cropper to a herd of barren weeds. Is this climatal or constitutional, or both? We have asked the question before, and hints like these may serve as a lesson against sweeping changes without a fair trial of comparison.

Raspberries are not in their natural element here. We have blinks of a torrid climate which tells heavily on our light sandy soil and subsoil. The Raspberry is at home in a soil inclined to be peaty in a rather shady position with plenty of moisture at the root. Currants and Gooseberries are plentiful, and of fair quality.

The effects of the weather, I am sorry to say, have also been felt to considerable extent in this neighbourhood in unheated and badly ventilated late houses, whilst those possessed of more modern structures complain as well. With glass houses and hot-water pipes we are supposed to be proof against any weather. Well, but are we? True, if we did not aim at succession crops the matter would be a simple one, but when fashionable people lay down rules for our guidance we have no other alternative than to follow them up to the best of our knowledge. We have, therefore, to open our ventilators in order to retard crops, and if there be a dry keen east wind on at the time, and a clear bright sky, as there generally is with the sun pouring down his rays, alternately with those sweeping cold winds when Phoebus is hidden for a time only to return with greater fury—if you arrange your ventilators for a change of dull weather all practical men will understand that the individual so circumstanced has not made his bed among Roses.

All that any one can do is to make the best of his position, A.'s case, though apparently the same as B.'s on paper, might be very different if all matters were put to a practical test. Visionary ideas are like cobwebs, you may warp them round an imaginary enemy, but the thread is delicate and will not bear much pressure. So it is with all matters in gardening; no one can give a sound opinion without he is first acquainted with all the practical details. Depend upon it there is a reason for everything; if there are empty Peach and orchard houses it was their inevitable and

irremediable fate consequent on the long continuation of biting east winds, over which no one has any control but the clerk of the weather; and whilst we are always ready to bow to superior knowledge and skill, and have no desire to explain away the credit due to those who are fortunate enough to have crops, yet I think it will be generally conceded that much depends on aspect, equipment, and other kindred matters which will be evident enough to the practical cultivator. We have had a busy time of it with insects, and do what we will we cannot effectually eradicate that greatest of all pests, black-fly. *W. Hinds, Otterspool.*

GREENHOUSE PLANTS.

THEIR CULTURE AND MANAGEMENT.

KENNEDYAS.—These are a handsome genus of evergreen conservatory summer blooming twiners, natives of New Holland and New South Wales. For a lofty conservatory the strong-growing species are well adapted, especially for draping the roof, for which their young drooping shoots, hanging in graceful festoons, are very effective. One advantage which they possess for growing in such positions is, that they will bear cutting-in freely, which is an advantage in the winter, when as much light as possible is required by the plants grown underneath. This is a consideration not sufficiently kept in sight in the selection of the kind of plants to be grown for roof climbers, betwixt which and the things that occupy the body of the house there must necessarily always be a compromise, as there is no question but that the climbers do more or less injury to the other plants, and are simply allowed to occupy their position to give a general effect to the house. There is a great difference in the strength of growth and general appearance of the different species, the smaller growers being more suitable for clothing a pillar than training to the roof. The strongest growers can with advantage be used for covering a back wall, in which situation they will succeed, even in partial light, much better than many things of more tender nature; they are easily grown, make rapid progress, and are not liable to get out of order at the roots to such an extent as many plants are, but, like some other subjects of similar nature, they do well when planted out. They are much better for being kept in a pot for a time until they have acquired sufficient strength of root to enable them to lay hold of the soil in a reasonable time after they are turned out, without which it is apt to get sour. When planted out the root room should be limited or increased according to the space the plant is destined to cover, a matter to which sufficient attention is not always paid in preparing the places for planting such things, and which afterwards gives trouble and causes a necessity for using the knife to an extent to keep them within the prescribed limits not consistent with their flowering in their wonted manner when the roots have too much room. In selecting plants that are intended for climbers it is always necessary to be particular that they are perfectly free from the worst species of insects, such as mealy-bug and scale, as when the things to be thus grown overhead are infested with these noxious insects they affect every plant that is grown under them, and by this means all get in a condition that entails an amount of labour such as could not be credited except by those who have had to contend with a collection of plants so affected. If healthy young plants in 6-inch pots are selected, they should in March or April be moved into others 2 or 3 inches larger, according to the quantity and condition of their roots. Kennedyas will thrive in either peat or loam; it is better to use the former for the weaker growing species, as it will impart a freer disposition of growth, confining the strong growers to loam, which should be good in quality, containing plenty of vegetable matter. They are comparatively strong-rooted subjects, and do not require the soil breaking very fine; add to it a fifth or sixth of sand, according to its nature; drain the pots sufficiently, as from the vigorous character of the plants they will need a good deal of water in the growing season. After potting place them for a few weeks, until the roots get hold of the soil, in a little closer atmosphere than an ordinary greenhouse, keep the atmosphere rather moist during this time, after which give more air in the early and middle part of the day, closing the house in good time, and syringing overhead, giving

water to the roots as required, when in active growth they will take a good deal. Continue this until the middle of August, when the plants should have more air, and cease syringing, to discourage further growth and ripen up the wood.

At the time of potting, half-a-dozen sticks, 3 or 4 feet long, should be inserted in the soil just within the rims of the pots, round these the shoots ought to be kept closely and regularly trained, as if allowed to twine to the supports, or become entangled with each other they are difficult afterwards to regulate without injury. They should be kept through the autumn and winter in a temperature of from 35° to 40° in the night, and 10° or so warmer in the day, but not so high as to excite any growth, or they will suffer when the roots are disturbed in planting out, which should be done before growth begins in the spring; the border in which they are to be planted may be from 1 to 2 feet in width, according to the greater or less space to be covered. It should have 4 inches of drainage in the bottom, consisting of crocks, broken bricks, pebbles, or anything of a similar nature, on which place an inch or two of fibrous material, over this put 10 or 12 inches of the soil, which should have a good quantity of sand mixed with it, and a sprinkling of crocks or charcoal will be an additional assistance in keeping it sweet. In planting disentangle the roots so far as can be done without injuring them, spreading them out and making the soil tolerably firm. Do not give water until it is required, which, if the soil at the time of planting is in right condition as to moisture, will not be nearly so soon as in a pot. Train the shoots in their places. I have said nothing about stopping—the necessity or otherwise for this will depend upon the number of shoots the plants have corresponding with the requirements of the situation. A single shoot to each wire will, in most cases, be preferable to more. They will require little further attention except water at the roots as needed, keeping the shoots from getting entangled, and a sufficient use of the syringe during the growing season to keep down aphides and red-spider. When they have filled their allotted space they will need the shoots reducing from time to time during the summer and in the autumn, cutting in as far as requisite. If they ever get affected with scale the best method of dealing with them is in the winter, when at rest, to partially head them down, cutting into the strong wood, untwining this from the wires, and steeping the whole down as near as can be got to the collar in Abyssinian mixture at 6 or 7 oz. to the gallon, repeating the operation two or three times in the course of a few weeks, before they have begun to break, brushing it well in about the collar of the plants. After cutting back thus severely they must not be over-watered at the roots, but much less given until they have made considerable progress. When the soil gets all exhausted an inch or two each spring may be removed and replaced with fresh, and manure-water during the growing season will also be a great assistance to them.

The undermentioned kinds are deserving of a place:—

K. Marryatta.—A handsome scarlet-flowered species from Australia.

K. Fredwoodii.—Also an Australian plant, a good grower, and free bloomer. Flowers red.

K. nigricans.—Flowers purple and green. It is from New Holland.

K. inophylla.—This is a fine scarlet kind. A New Holland species.

K. rubicunda.—A strong growing kind from New South Wales. Flowers deep red.

K. monophylla.—Also a strong growing sort from New South Wales. It has purple flowers.

K. Makoyana.—A Swan River plant, with scarlet flowers. A free grower.

K. ovata purpurea.—Is from New Holland. It has purple flowers. *T. Baileys.*

RAPID RISE OF WATER IN PLANTS.

In carrying out some experiments for another purpose, I was so surprised at the rapid recovery from a withered condition of some plants to perfect freshness and the normal position of the leaves, that I determined to undertake others for the express purpose of noting the actual time taken up by different plants in regaining a fresh condition. I will give the results in the case of some Raspberry-caness as an example. My first cane was cut at 10.10 A.M. on a cloudy

day. It was a vigorous cane in a growing state, 4 feet 4 inches high, bearing twenty-five leaves, three or four of the lower of which were beginning to change yellow; and it soon began to wither, attached, as it was, in an erect position in my study with the window wide open. At noon all the leaves were flaccid, the upper young ones very much withered, and the growing tip of the cane drooped about 5 inches. After waiting until 12.10 P.M., to make up two full hours since it was cut, it was fixed in an erect position in a tumbler of water, the water being 3½ inches deep. The cane touched nothing except the cross bar to which it was loosely tied in an erect position with the curve of the drooping tip towards the light. By 12.20 I was surprised to find that nearly all the leaves had regained their normal rigidity, and I then set myself to watch the conclusion of the experiment. I was more than surprised, I was astonished at what I then witnessed. As I have already stated, the tip of the cane was 5 inches lower from drooping than when the cane was cut. At 12.10 this tip had scarcely begun to rise, but by 12.30 it had regained its normal position, though it was not, and never became, quite so rigidly erect as it was before it drooped at all. This I attributed to the action of the attraction of light. However, I shall be within the margin if I say that the tip rose at least 4 inches in the whole twenty minutes, and at least 3 of these 4 inches during the last ten minutes. The movement was indeed so quick as to be distinctly visible. Leaflets unfolded, petioles spread themselves out, and the stem gradually rose, until it was nearly quite erect. Thus, in this short time the tip of the cane described nearly a quarter of a circle, and the leaves on the outside of the curve passed through nearly half a circle. Consequently the water must have passed from cell to cell almost as rapidly as it is diffused through a lump of sugar. Not having any suitable apparatus I could not determine the exact quantity of water absorbed by this cane during the twenty minutes the experiment lasted, but from measurement and calculation, 1½ cubic inches may be regarded as an approximation to the truth.

At the same time as I cut the Raspberry cane, or within half a minute at most, I cut a stout stem of Jerusalem Artichoke, about 5 feet high, bearing thirty-three leaves, most of which were a foot long and 4½ to 6 inches broad in the middle. This was put into water at the same time as the Raspberry-cane, but from its more herbaceous nature it was much more withered, and never recovered. In this case, although the bottom of the stem was twice cut, it was wholly unable to take up sufficient water to fill the plant, as the evaporating surface was so great. With a second Raspberry-cane, cut the same day at 12.55 P.M., I attempted to decide two questions, firstly, whether the fluid imbibed by the plant actually mounted to the top in so short a period as that occupied by the first cane to recover from the withered state; and, secondly, whether one-half of the circumference of the stem only being in the water, would be able to absorb sufficient for the needs of the leaves all around the stem. The first problem I failed to solve, probably because the colouring matter I used was refused by the plant. The only thing I had in the house that I thought would answer my purpose was port-wine; but, as I wanted to use the same quantity as I had of water alone in the first experiment, to save my wine I simply added sufficient to colour rather deeply the tumbler of water.

To the second question my experiment gave me an affirmative answer. The second cane was even more robust, though shorter-jointed than the first, was in more active growth, and bore as many leaves, but it was only 3 feet 9 inches high. After splitting the stem in half from the base about 6 inches upwards and removing one-half, this cane was put into the tumbler of wine-and-water, and mixed in the same manner as the other, at 2.35. Although this cane had been cut only an hour and forty minutes it was perhaps rather more withered and flaccid than the first became before putting it into water, and the tip had drooped about 5½ inches. The process of recovery was very slow, and it would be useless to describe it here; suffice it to say, at 5.35 the leaves had regained their normal position, and the tip of the cane was erect. I may add that the curve of the droop was turned from the window.

In order to ascertain how high the coloured liquid had risen I cut them through in various places, but I could not detect the slightest trace of my wine, even in the part that was actually in the mixture. To

test this more thoroughly I used my first cane, which had been lying on the floor from 1 to 6.35 P.M., and was very much withered, again; before putting it into the wine-and-water I cut it at the base, as in number two, and also took a piece out halfway through the stem on the opposite side a little higher up, so that practically the stem was completely severed. At 10 o'clock the same evening it had nearly recovered, and promised well for complete recovery, but after twenty-four hours it was still a little flaccid at the tip, and probably if the weather had been dry it would most likely have been in a worse state. No trace of the colouring matter could be found in this cane. *W. B. Hemsley.*

ADELAIDE BOTANIC GARDEN.

DR. SCHOMBURGK in his report on the condition of the Adelaide Botanic Garden for 1876, remarks that the climate of that city is one of extremes:—Our annual average fall of rain is 21 inches, and last year only 13.434 inches fell—being the least ever registered. The driest season before was in 1859, when 14.460 inches fell. Until the month of August only about 8 inches had been registered, and the worst was feared for our crops, but fortunately, during the months of September, October, and November, 3.571 inches more fell, which saved the Wheat crops in some of the districts. During December the heat in Adelaide had been very great for the first five or six days, but on Thursday the 14th it was almost unendurable at about 3 o'clock, when the thermometer registered 114°.2 in the shade, and 162°.6 in the sun; which was the highest reading registered since January, 1862. This degree of heat has only been exceeded on three former occasions, viz., January 20, 1835, when the thermometer registered 116°.3, and the 9th and 14th of January, 1862, when the reading for both days was 115° in the shade. This unusually dry season would have proved very destructive to our young plantations, especially in the park, where within the last two years 9000 trees have been planted, but for the attention paid to them, and the free supply of water—nearly our whole staff of men having been employed during November, December, and January in watering. I am glad to say that we have saved them nearly all, as I consider the loss of last season's planting not quite 2 per cent. The trees from colder climes, such as North America, Europe, and New Zealand, always suffer most. But the greatest enemy the garden had to contend with was the heavy frost. The lowest temperature during the month of July was 28° Fahr.—the lowest I have experienced in South Australia. These severe frosts have had a most disastrous effect upon the garden. The tropical and sub-tropical plants, especially tropical Ficus, constituted the chief bulk of the sufferers, and that to such an extent as would be hardly credited by those who have not seen the injury done.

Palm-house.—The building and interior arrangements of this structure have been completed. The opening ceremony was performed by Lady Musgrave on Monday afternoon, January 22, and it is highly gratifying that there is but one opinion with regard to the undertaking and the artistic appearance.

I think it is not out of place to give a *resumé* of the work performed regarding the house during the last year. The ironwork and glass arrived during December, 1875, from Bremen, in very good condition; and it is only just to mention that the workmanship of both the wrought and cast iron was considered by competent judges as faultless. The forty-two cases of glass, I am sorry to say, had suffered considerably on board the vessel—nearly one-third of the bulk having been broken, for which compensation was made by the captain of the vessel.

As already mentioned in my former reports, to insure a striking effect it was found necessary to erect the building on a terrace of about 6 feet high and 30 feet broad on all sides of the house; 20 feet of this terrace are formed into a walk, and the remaining 10 feet into a flower border, surrounding the walk. The building of the foundation of the house was very expensive, as it had to be laid into firm ground; on one part of the side on which the house stands a lake was intended to be formed, and a large part of the soil had already been excavated to a depth of 4 to 5 feet. The idea was afterwards abandoned, and the excavation filled up with soil and debris—thus greatly adding to the expense of the foundation, which in some places is from 8 to 9 feet deep. Three horses and

drays, and ten men were occupied twelve weeks with sloping, excavating, loading the drays, and removing the soil to the terrace, and about 100 loads of turf Couch-grass, *Cynodon Dactylon*, were used for turfing the terrace. The turfing, notwithstanding the unusual dry season, has fortunately answered as well as could be expected. Two flights of steps on the north and south sides of the terrace, 12 feet broad at the top, and 30 feet at the base, with a neat coping, lead up to the terrace; at the bottom, on each side of the steps, are placed two vases, and on the summit tasteful pedestals, bearing on the northern sides statues of Ceres and Clio, and on the southern Flora and Pomona. The statues and vases have been procured from the celebrated firm of Castener & Co., Berlin, which, from their exquisite workmanship, are real objects of art. The cost, freight included, was £100. The steps are of Mintaro slate, and the cost of building, £260.

The interior arrangement of the house is as follows:—Both ends of the house terminate in a half octagon; in the eastern one a basin and fountain have been placed, surrounded by a fine collection of Ferns—*Dicksonia antarctica*, *Alsophila Cooperi*, and *A. Leichardiana*. In the front of the basin are planted the following smaller kinds, viz., *Adiantum amabile*, *concinnum*, *farleyense*; *Gymnogrammas*, *Lomarias*, *Blechnums*, *Pteris*, &c. The empty space between

which, when in its former place, filled the rotunda of the conservatory. Round this noble Palm is formed a large group, principally variegated leaf-plants. The group measures 50 feet in circumference on its base, and is bordered by an ornamental tastefully coloured border worked in cement. This majestic group is a striking object, which, upon entering, attracts the eye at once. An avenue 6 feet wide runs from one extremity of the house to the other, traversing round the centre group and both entrances. Both sides of the straight walk are lined with Fern trees of equal height (6 to 7 feet) from New Zealand, Port Natal, and Queensland, and contain the following specimens, viz., *Cyathea dealbata*, *Dregii*, *excelsa*, *medullaris*; *Alsophila Cooperi*, *Leichardiana*, *australis*; *Dicksonia antarctica* and *Youngiae*. These have been the only plants specially bought for the Palm-house.

The walks are skirted with an ornamental border about 2 feet high, composed of bricks and cement, with a tasteful coping, so that the walks afford as much space as possible for the accommodation of the numerous visitors, especially on Sundays and holidays, when the house is crowded, and at the same time, not to encroach upon the space for the plants, the border juts in and out at right angles forming a pattern *à la grec*. The floor is tiled with red and blue octagon tiles, which produce a very pleasing effect.

FIG. 26.—AGAVE FLACIDA.

these Ferns is planted with *Lycopodium*, which has grown so luxuriantly that it forms a splendid green carpet. In the western octagon is constructed a grotto from stalactite, specially imported from the Black Forest in Germany. The grotto is about 10 feet high and 8 feet broad. At the back of the grotto there streams, over quartz and sandstone rocks, a cascade, into a small basin. The large pieces of stalactite are put together in a wild and irregular manner, and the effect produced is striking. The top of the grotto is embellished with *Dracænas*, Palms, &c., intermixed with climbers, viz., *Antigonon leptopus*, *Cissus discolor*, *Asparagopsis javanica*, *Echites rubrovenosa*, &c., which hang in festoons over the stalactite. The interior wall of the grotto is planted with *Philodendron daguense*, *melanochrysum*, *Pothos argyrea*, *macrophylla*, &c., growing on the stalactite, and spreading their handsome leaves symmetrically. Around the basin are placed a number of the most handsome leaf-plants, viz.:—*Dieffenbachias*, *Phyllo-tænium Lindenii*, *Spathiphyllum*, &c.; and on both sides of the grotto are grouped a number of rare and handsome Ferns, viz., *Adiantum peruvianum*, *gracillimum*, *concinnum*, *cardioclæna*, *speciosum*, *prionophyllum*, *excisum*, *fovearum*, *Hendersonii*; *Davalia tenuifolia*, *Moorei*; *Gymnogramma*, *Cheilanthes*, *Pteris*, &c. Two fine specimens of *Alsophila Cooperi*, the stems 6 feet high, adorn both sides of the grotto, which produces a pleasing aspect.

The central plant of the rotunda is a magnificent specimen of *Latania borbonica*, about 16 feet high,

The broad beds extending alongside both sides of the walk are filled with the choicest plants, especially Palms, partly planted in the soil and partly in pots. I will only mention the most noteworthy, viz., *Cocos Weddelliana*, *coronata*, *flexuosa*; *Martinezia erosa*; *Eleis guineensis*; *Ceroxylon niveum*, *andicola*; *Areca Nenga*, *Nibung*, *Catechu*, *monostachya*; *Ænocarpus Bacaba*, *Penanga*, *Kuhlii*; *Zalacca edulis*; *Dæmonorops fissus*, *palempanicus*; *Pritchardia macrocarpa*, *pacifica*; *Thrinax brasiliensis*, *parviflora*; *Astrocaryum Malybo*, *Murumuru*; *Maximiliana regia*; *Orbignya dubia*; *Kentia Forsteriana*, *Belmoreana*, *Thrinax elegans*, *Cecropia*, *Paratropia*, *Musa*, *Cycas*, *Aralia*, *Ravenalia*, *Heliconia*, &c.

The twelve brackets which support the roof and sides of the wings of the houses have been planted with choice collections of climbers, viz., *Petræa*, *Stigmaphyllon*, *Combretum*, *Antigonon*, *Allamanda*, *Stephanotis*, *Passiflora*, *Tacsonia*, *Aristolochia*, *Jasminum*, *Clerodendron*, &c. Considering the luxuriant growth since planted, they will soon reach each other and form a green dome, which will greatly contribute to shading and cooling the house. The eight graceful pillars which support the rotunda have also been supplied with climbers. A shelf runs along the windows of the house, on which are placed smaller and tender plants, which produce a fine effect from the terrace through the glass.

The ventilation is also perfect. Two rows of ventilators are placed on the sides, and a row on the roof, which are easily worked by pulleys and ropes,

The rotunda, with its recesses and corners, cannot be shaded by blinds; and to protect the plants from the burning rays of the sun the glass has been frosted. The large surface of glass exposed to the sun, notwithstanding the shading and frosting, produces great heat in the house, and on hot days every precaution is necessary to keep the temperature down. In fact, the effects of the sun on thick glass acts like a burning-glass, so that the leaves of the plants exposed to it have been burnt. During our unusually hot weather every attention was required to prevent such injury, especially on days when the thermometer showed 163° in the sun and 114° in the shade; but I am glad to say very little injury was done to the leaves. We have now gained experience to prevent a repetition in future. When the climbers have covered the roof this will lessen the heat, and will give more shade.

The trials of the heating apparatus gave great satisfaction. The boiler is one of Messrs. Holme & Partington's, Manchester, tubular boilers, No. 2, about 18 inches in diameter and 5 feet high, heated with coke, which was warmly recommended by Mr. Rothermund, Bremen, who uses the same in his Palm-house. Considering the great cold they have to contend with in Germany, Mr. Rothermund feared that one boiler would not be sufficient to produce the required heat, so he put up a second reserve boiler; but even during the coldest time one boiler warmed the house. The boiler is placed on the western side of the house, in a 7 feet deep excavation, reached by steps. Two rows of 4-inch iron pipes traverse both sides of the house, ending in two cisterns in both corners of the eastern wing. The length of the pipes is 443 feet. To prevent accident one of the cisterns is provided with a safety-valve. The chimney is scarcely observable; a copper tube is fixed on the corner pillar. The trial of the heating apparatus showed that two small buckets of coke, in the course of half an hour, made the water boil in the cisterns—a distance of 104 feet from the boiler.

As the extensive surface of the roof will produce, during heavy rain, a considerable rush of water, large gutters have been provided, and by means of 204 feet of iron pipe the water is led from the terrace on the eastern side into the small lake on the western side. It irrigates the lawns. A lightning-conductor has been fixed on the rotunda.

I think that nothing has been overlooked, and everything has been carried out as practically as possible.

In fact the interior of the Palm-house appears as if the plants had grown there for years; and it is like a fairy tale of the "Thousand and One Nights" that in so short a time the house has been embellished with such magnificent and valuable specimen plants, the number of which is 1145. At the same time it is a riddle to the public where these fine plants had been before stored.

No doubt the whole undertaking is a great success; but as there is nothing perfect in the world so it is with our Palm-house—it should at least be twice as large. In a few years, by the steady increase of tropical plants, the house will be overcrowded, and the noble Palms will soon have reached the roof.

The cost of the ironwork and glass, including freight and commission (it had to be transhipped in London), delivered in the garden, has been about £1300, and the cost of building the foundation of the terrace, flight of steps and statuary, has been about £2500, making a total of £3800. This does not include the work of painting and glazing, which has been carried out by some of the workmen employed in the garden, under the direction of a professional painter, who is also expert in glazing, and an employed of the garden. The assistance of our labourers at the work has also not been taken into account.

THE GENUS AGAVE.

(Continued from p. 41.)

SERIES I.—CORIACEO-CARNOSÆ.—Texture of the leaf rigid, not at all fleshy nor yielding to the touch when mature; end-spine large, hard, and pungent.

Group IV. AMERICANÆ.—Edge of the leaf without any distinct horny border. Teeth large, deltoid-cuspidate, comparatively few in number.

In this paper I propose to deal with the dwarf species of this group with oblanceolate leaves, leaving till next time the larger kinds.

33. *A. flaccida*, Jacobi, Monogr., p. 226, (fig. 26); *A. cuspidata*, Hort. Saunders.—Leaves 40—50, in a dense rosette 1½ foot broad, oblanceolate-spathulate,

3 inches broad three-quarters of the way up, narrowed to 1½ inch above the dilated base, glaucous green, the face flat throughout; the hard, pungent end-spine 1 inch long, and decurrent a little; the crowded prickles ¼—½ inch long, deltoid, with a large cusp, slightly hooked downwards. Inflorescence unknown.

A native probably of Mexico. I am acquainted with Jacobi's plant from the description alone, which matches very well the plant called *A. cuspidata* in the Saunders' collection, from which our drawing was made. Whether this be the same as *A. rubescens*, Salmdyck, Kunth, Enum., vol. v., p. 835, I have no means of knowing except from the description. Our present plant is midway between *A. macracantha* and *Scolymus* var. *ameena*.

34. *A. viridissima*, Hort. Peacock.—Acaulescent. Leaves about 30 in a rosette 2 feet broad, oblanceolate-spathulate, 1 foot long, 3 inches broad three-quarters of the way up, narrowed to 2½ inches above the dilated base, where it is ½ inch thick, very rigid in texture, bright green, not at all glaucous, the centre ½ inch thick, the face flat, the end-spine hard and pungent, nearly 1 inch long, the close grey spreading unequal prickles ¼—½ inch long, slightly curved upwards in the upper half of the leaf. Inflorescence unknown.

A native probably of Mexico. I have seen it only in Mr. Peacock's collection. It is a very distinct-looking plant, well marked in the group by its thin rigid bright green leaves.

35. *A. (Littæa) utahensis*, Engelm. in S. Wats. Bot. 40 Parall., p. 497; Notes, p. 20.—Acaulescent. Leaves ensiform, 6—12 inches long, 12—21 lines broad, thick, glaucous, the channelled pungent end-spine about 1 inch long, the deltoid teeth ¼—½ inch long, white with a

FIG. 27.—AGAVE MACRANTHA.

darker base. Scape 5—7 feet high, including the 1—2 feet spike; peduncles finally ¼ inch long; pedicels shorter. Perianth yellowish, including the ovary about 1 inch long; tube very shallow; segments 3—4 times the length of the tube; stamens inserted at the middle of the tube; filaments little exerted, ¾ inch long; anthers ½ inch long. Capsule oblong-trigonal, about 1 inch long; seeds ¼—½ inch broad.

A native of Southern Utah and Arizona, not yet known in cultivation. It reaches the furthest north of all the Agavoid plants.

36. *A. macracantha*, Zucc.; Jacobi, Monogr., p. 92.—Acaulescent or shortly caulescent. Leaves 30—50 in a stiff rosette 1—2 feet broad, oblanceolate, 6—12 inches long, 1—1½ inch broad above the middle, narrowed to 1 inch above the dilated base, where it is ½ inch thick, very stiff and rigid, very glaucous, the face rather turgid in the lower half, the centre ¼ inch thick, the end-spine nearly black, very pungent, ½—¾ inch long, the purplish-black subsistent prickles ¼—½ inch long, deltoid, with a large cusp straight or slightly hooked. Scape 2—3 feet long; bracts erect, lanceolate-acuminate, growing gradually smaller upwards. Flowers 10—12 in a lax raceme ½ foot long, all solitary on ascending pedicels ¼—½ inch long, which are usually bracteolate near the tip. Perianth greenish, 2 inches long including the ovary. Ovary oblong, 1 inch long; lobes about three times as long as the tube. Filaments exerted about ½ inch; anthers ¾—1 inch long.

A native of the mountains of Mexico, ascending to a height of 5000 or 6000 feet. It seems to have been known in cultivation since about 1830, and is now widely distributed. It is marked by its stiff dwarf habit, and its nearly black spines form a very effective contrast in colour with its very glaucous leaves. It runs into numerous varieties and I cannot separate specifically *A. flavescens*, Salmdyck, Jacobi, Monogr., p. 91; *A. Besserrariana*, Jacobi, Monogr., p. 92 (two

forms figured *Gardeners' Chronicle*, 1871, p. 75, and in flower Bot. Mag., t. 5940); *A. subfalcata*, Jacobi, *Nachtrage*, 2, p. 75; and *A. linearis*, Jacobi, *Nachtrage*, 2, p. 76. There is a full account of it in the *Botanical Magazine* from a plant that flowered with Mr. Saunders in the spring of 1871. It recedes from the ordinary *Littæa* type of inflorescence in having all the flowers single, and it will be interesting to ascertain how far this character is maintained on further acquaintance. Our present (fig. 27) drawing represents the form that is widely cultivated both in English and Continental gardens under the name of *A. Besserrariana candida*.

37. *A. concinna*, Baker; *A. saaburyensis*, Hort. Peacock.—Acaulescent. Leaves about 30 in a stiff rosette 1½ foot broad, oblanceolate-spathulate, 7—8 inches long, 2 inches broad at the middle, narrowed to 1½ inch above the dilated base, where it is ½ inch thick, the face flat, slightly glaucous, the centre ¼ inch thick, the pungent end-spine nearly 1 inch long, the subsistent much hooked deltoid-cuspidate prickles about ¼ inch long. Inflorescence unknown.

Country unknown; probably Mexico. I have seen the plant only in Mr. Peacock's collection. It differs from *macracantha* in the shape, thickness, and colour of the leaf and character of the prickles. *J. G. Baker*.

INFLUENCE OF LIGHT ON PLANT GROWTH.

IN consequence of a remark made by Dr. Gilbert at one of the meetings last year of the Scientific Committee of the Royal Horticultural Society, the question of the influence of light on the growth of plants was discussed in several communications by different contributors to the *Gardeners' Chronicle*, but the subject dropped at the time without having received the attention it deserved. I am induced to reopen the discussion, not because I have any new facts of my own to offer, but because I think a sketch of the present position of our knowledge may be acceptable. It is necessary in the first place that we should perfectly understand what is meant by the assertion that light is antagonistic to growth, or we shall probably find ourselves discussing the same question from different standpoints. Indeed, it was perhaps through a misconception of a statement made by Mr. Dyer which appeared in the *Gardeners' Chronicle* (vol. v., new series, p. 722), that Dr. Gilbert was led to bringing the topic under the consideration of the Scientific Committee. But I ought to say that I have no authority for advancing this opinion, as Dr. Gilbert may have, for aught I know, sufficient grounds to refuse to accept the assertion that light is antagonistic to growth in any qualified sense whatever. Mr. Dyer, in the place quoted above, simply gave the general bearings of the results obtained by Sachs and others in their investigations on the laws of growth, and in all these investigations temperature, moisture, and other conditions, played important parts. He there states that "varieties in the normal rate of the longitudinal growth of stems appear to be produced by variations in the external conditions of moisture, temperature, and light. Taking intervals of time as abscissæ, and increments of temperature and growth as ordinatæ, the curves of temperature and growth (formed by connecting the ends of ordinatæ) are found to follow one another, rising and falling together, without, however, being related in any more definite manner. The influence of light is quite of an opposite kind—it is antagonistic to growth. The curve of growth will, therefore, have a maximum during the night and a minimum during the day; but the rate of growth exhibits a certain inertia, light only gradually checks it, so that the minimum is towards evening; and similarly the absence of light gradually stimulates it, so that the maximum is towards morning." But, from what follows, it will be seen that it is only when the temperature is nearly uniform day and night that growth proceeds in the manner here described. Lindley, writing in 1842, expresses it as his opinion that there are other influences not yet detected at work governing the fluctuations in the growth of plants; and Reinke, in his latest investigations, seems to have encountered the same difficulty in accounting for the phenomena of growth. In all cases the influence is supposed to be limited in its action on the extension or growth of plants, as distinguished from assimilation. Some details of Reinke's experiments, just alluded to, are given in the *Gardeners' Chronicle*, new series, vol. vi., p. 103.

That light is really antagonistic to growth under any conditions there is still room for doubt, and it is equally true that light under certain conditions has not the power to prevent growth, and rapid growth. Therefore the assertion that light is antagonistic to growth seems too absolute, even if opposed to the attribute of heat, unless we are to assume that, because plants do not grow, or do not grow so rapidly, under certain conditions of illumination that light is the cause. Before adducing arguments in support of any particular theory let me give a summary of the results obtained by some of the most careful enquirers. While accepting their results, we are still at liberty to reject any or all of their deductions.

PERIOD OF GROWTH.

Numerous experiments have been made to determine the period of the twenty-four hours during which plants exhibit their greatest intensity of growth. By growth, here, elongation or extension of the axis is to be understood. A complete history of the subject will be found in the *Adansonia*, vol. ix., p. 203, by Rauwenhoff, and in the *Arbeiten des Bot. Inst. in Würzburg*, 1872, by Sachs. But neither of these writers mentions the experiments conducted by Dr. Lindley in the Horticultural Society's garden at Chiswick, and recorded in the *Transactions of the Society*, vol. iii, new series, p. 103 and p. 247. Among the earliest observations of this kind on record are those by Ventenat (1793) on the rate of growth of the flower-stem of an old *Fourcroya gigantea* at Paris. This attained a length of 22½ feet in seventy-seven days, and made more growth during the day than during the night, and grew fastest on the hottest days.

In 1828 Professor E. Meyer, of Königsberg, published some careful observations on the periodic growth of plants. The first related to the growth of the peduncle of *Amaryllis helladonna*. The peduncle, he tells us, was measured three times daily, namely, at noon, at 6 P.M., and at 6 A.M., with the general result that the growth was much more rapid by day than by night. Respecting a series of observations on the growth of Wheat and Oats, he found the growth invariably greater between 8 A.M. and 8 P.M. than during the night. And according to his observations these plants showed a greater energy of growth between 8 A.M. and 2 P.M. than during the succeeding six hours.

Observations by Professor Mulder, published in 1829, on the growth of the leaves of *Urania speciosa*, gave a contrary result. His measurements were almost hourly from 5 A.M. to midnight, and they showed that there was considerably more growth during the night.

A few years later De Vriese took measurements of the growth of the flower-stems of two plants of *Agave americana*, near Haarlem. One of them attained a length of about 24 feet in seventy-one days, and in both plants, with the exception of a few days, the nocturnal growth was constantly less than the diurnal growth. In 1847 the same botanist made some further observations, in which the sum total showed the greatest growth for the day, though towards the end the nocturnal growth exceeded the diurnal.

Dr. J. Münter (*Botanische Zeitung*, 1843) recorded a series of careful observations of the elongation of the common peduncle of *Pelargonium triste*. In this case again the growth was greater during the day than during the night. But in some experiments with other plants he observed the reverse was the case.

About the same date Professor Hartig took measurements of the growth of a Hop plant at 7 A.M., 3 P.M., and 11 P.M., and took simultaneously barometrical, thermometrical, and other observations. During the first part of the experiment the greatest energy of growth was between 7 A.M. and 3 P.M., but later on, when the total rate of growth had begun to decrease, it was between 3 and 11 P.M.

An experiment by Wells, of Lümburg, with *Agave Jacquiniana*, from April 3 to May 25—measurements taken at 6 A.M., at noon, and at 10 P.M.—gave for the first period (eight days, April 3 to 12), greatest growth during the night; for the second period (ten days, April 12 to 22), greatest growth during the afternoon; third period (seven days, April 22 to 29), morning; fourth period (seven days, April 29 to May 6), night; fifth period (thirteen days, May 6 to 19), morning; sixth period (six days, May 19 to 26), greatest growth during the night. Altogether there was a greater total growth in length during the day, and in diameter during the night.

During the latter part of the summer of 1865, Duchartre observed the growth of several plants, and in each case the total night growth greatly exceeded the day growth. To give an example or two. *Vitis vinifera* grew between August 6 and September 8, 447.5 millimetres (nearly 20 inches), whereof 164 or 36.6 per cent. during the day, and 283.5, or 63.4 per cent., during the night. In *Fragaria*, total growth for the day was 33.7 per cent. against 66.3 per cent. for the night. *Humulus Lupulus*, *Althæa rosea*, *Gladiolus gandavensis*, furnished similar results.

In the following year—1866—at Montpellier, Professor Martius recorded the nightly and daily growth of the inflorescence of *Dasyliion gracile* from June 1 to 23. The total growth was 2.881 metres, of which 1.266 metres was made during the night, and 0.793 during the day, the total night growth to the day being as 1 : 0.61. A plant of *Phormium tenax* exhibited the same phenomena.

Rauwenhoff, in the place quoted above, records a long series of observations taken under the most variable conditions of the weather, and varying very much as to the period of the greatest energy of growth; but, confining ourselves to the total during the whole period by day and night, divided into two equal periods of twelve hours, there is in the case of each plant observed a considerable percentage in favour of the day. The following are some of the figures given by Rauwenhoff :—

Bryonia, total growth 1276 millimetres, whereof 753, or 59 per cent., by day, and 523, or 41 per cent., by night. *Wistaria*, total growth 3414 mm., whereof 1976, or 57.8 per cent., by day, and 1438, or 42.2 per cent., by night. *Vitis*, total growth 2372 mm., whereof 1306, or 55.1 per cent., by day, and 1066, or 44.9 per cent., by night. *Cucurbita*, total growth 6102 mm., whereof 3491, or 57.2 per cent., by day, and 2611, or 42.8 per cent., by night.

Dr. Lindley's experiments (*Transactions of the Royal Horticultural Society*, new series, vol. iii., p. 103 and p. 247) were of two series, the one conducted in a stove, in which the average day temperature was 73° and the night temperature about 65°, and the other in the open air, during the months of August and July in front of a vinery. The first series was on *Salix pentandra*, *Ficus Carica*, *Passiflora onychina*, and *Vitis vinifera*. Measurements were made four times during the twenty-four hours, namely, at 6 A.M., noon, 6 P.M., and 11 P.M. As may be seen from the accompanying table, copied from Dr. Lindley's paper, there was no uniformity in the behaviour of the different plants employed, and that the rate of growth was maintained, with the exception of *Passiflora onychina*, at something approaching regularity during the whole of the twenty-four hours; and it is a singular fact that each plant made its maximum growth during a different quarter of the twenty-four hours. The growths are given in inches and decimal fractions :—

Names of the Plants Employed in the Experiments.	12 P.M. to 6 A.M. Morning.	6 A.M. to Noon. Forenoon.	Noon to 6 P.M. Afternoon.	6 P.M. to 12 P.M. Night.
<i>Salix pentandra</i>	9.37	11.13	10.42	9.71
<i>Ficus Carica</i>	4.37	4.88	5.04	5.23
<i>Passiflora onychina</i> ..	18.0	13.41	22.44	18.20
<i>Vitis vinifera</i>	18.13	17.24	17.21	16.02
Total growth during the experiments ..	49.87	46.66	55.11	49.16

The second series was conducted out-of-doors during the months of July and August, upon the Hop, Grape Vine, Jerusalem Artichoke, Gourd, Sweet Willow, Scarlet Runner Bean, and Fig; and the measurements were taken at 4 A.M., noon, and 8 P.M. Of all these plants the Grape Vine was the only one that made its greatest growth during the darkest period of the twenty-four hours, that is from 8 P.M. to 4 P.M., and this only during the month of July. All the others showed the greatest energy of growth during daylight, and the majority between noon and 8 P.M. The total growths of all the plants taken together during the two months were, between 8 P.M. and 4 A.M., 119.07 inches; between 4 A.M. and noon, 156.26; and between noon and 8 P.M., 180.90. Observations on the weather were made simultaneously, and special attention was given in elaborating the results to the influence of light on growth. Dr. Lindley himself was greatly surprised at the results obtained, and with regard to light he says, in the

* A seventh was deducted from this, and added to the fourth column, to equalise the periods.

concluding remarks of his second paper—"It does not seem desirable to extend these tables further, for if the observations are analysed for the effects of wind or bright light, there are the same inexplicable discrepancies. Indeed, the average of the afternoon growth being so much higher than that of the morning and night, as is shown in the table at p. 255, seems to render an examination into the effects of light superfluous; for it must be admitted that on an average we have more light between noon and 8 P.M., the time of the afternoon observations, than in either of the other periods."

GENERAL CONCLUSIONS.

From the foregoing figures it will be seen that no general law appears to obtain with regard to the period in the twenty-four hours during which plants develop their maximum intensity of growth. It varies for the same plant, according to circumstances, and especially, it would seem, according to its stage of growth and general rate of growth; and it varies for different plants in the same stage of growth, and subjected to the same conditions at the same time. Nor do these figures indicate that light is antagonistic to growth, as distinguished from assimilation. But experiments made by Sachs, under artificial conditions in which he could control the amount of heat and moisture whilst retaining the normal conditions of light, gave gradually increasing increments of growth from sunset to sunrise, then gradually diminishing until they reached the minimum at sunset. This, however, only proves that with increasing light there must be a corresponding rise in the temperature to maintain active growth; and that too high a temperature in darkness, or subdued light, stimulates an excessive elongation of the internodes. Plants assimilate and grow under the influence of light, provided the heat is sufficient; in darkness they continue growing at a lower temperature, until they have exhausted their assimilated food. When the state of darkness or semi-darkness is unduly prolonged plants make a great effort to reach light by developing extraordinarily long internodes. That plants will flourish and quickly attain maturity in almost continuous light is proved by the vegetation of high latitudes; and in the equatorial regions the rains govern to a greater extent the growing season of plants. Observations on the day and night growth of plants in tropical countries would be exceedingly interesting. If, as has been asserted by some, these islands in past ages enjoyed a warmer climate than now, and supposing the hours of sunlight to have been the same as at present, would that in any way account for the prodigious vegetable luxuriance exemplified in the coal measures? In the tropics the rainy (growing) and dry (resting) seasons differ more in humidity than in anything else. With us the greatest amount of light, heat, and growth go together, but if the temperature falls below a certain point the light alone is insufficient to promote growth and most likely assimilation also. On the other hand, with favourable conditions of light and heat during the day, the plant assimilates sufficient food to enable it to continue growing until the return of light and heat. The plant, so to say, is asleep, but sleep does not necessarily arrest growth. A certain amount of heat and moisture combined will promote growth, but not sustain it, whereas the addition of light, without retarding growth, enables the plant to find and cook its food, and continue growing.

HIGH NIGHT-TEMPERATURE DETRIMENTAL.

A knowledge of these facts is important from a practical point of view, as they go to show that a continuously high night temperature is prejudicial to the healthy growth of plants; it stimulates without feeding, and finally overtakes the energy of the plant. The real meaning then of the assertion that light is antagonistic to growth is, that if the temperature is as high during the darkness as during the daylight, then growth will be more active by night than by day. Have experiments yet proved that this disturbed relation of light and heat could be successfully adopted in practice, or that a plant will flourish and reach maturity under such conditions? I think not, and if they have not it seems to me that it is stretching a point to say that light is antagonistic to growth, simply because plants grow equally as well for a short time in the dark. Excessive heat and light together sometimes retard growth, and possibly the greater nocturnal growth is sometimes to be accounted for in this way. Doubtless we have much yet to learn as to the sepa-

rate and combined influences of light, heat, moisture, &c., and what are the most favourable proportions of each for any given plant. But darkness should be regarded by the horticulturist, as it is indeed by good practical men, as a period of rest, when the temperature should be allowed to fall considerably below a normally good day temperature, in order to avoid stimulating unhealthy weakly growth. *W. B. Hemsley.*

THE FULHAM NURSERY.

THIS is one of the oldest of the old London nurseries, having existed as a scientific garden and nursery upwards of 200 years. In the history of Fulham we read that the Fulham Nursery and Botanic Garden was established by Messrs. Ferbur & Gray, the most eminent nurserymen of their time. It has a world-wide reputation for rare trees, many of which were contributed by Catesby, Collinson, Miller, and other botanists and travellers, which were added to by Bishop Compton's noted collection. For many years it has been in the hands of the Messrs. Osborn and their family.

DECIDUOUS TREES.

Lovers of rare trees will here see many old examples such as are seldom to be met with. Amongst trees of a weeping habit particularly noticeable is the Japanese Sophora (*Sophora japonica pendula*), here represented by a couple of venerable specimens, very distinct and handsome. Near them is a splendid example of the North American medicinal *Sassafras* (*Laurus Sassafras*), from which the *Sassafras* chips are obtained. It is an old tree, the bole thick and rugged. The Chinese *Magnolia conspicua* is also to be seen, and not far from it stands *M. Thompsoniana*, a hybrid betwixt *M. tripetala* and *M. glauca*, and which has the fine perfume of the latter. The Judas tree (*Cercis siliquastrum*) is represented by a good specimen. *Pyrus arbutifolia* was at the time of my visit (in the autumn) in splendid condition, the leaves as highly coloured as those of the snowy *Mespilus* in the last stages before they fall, the *Pyrus* having the advantage in retaining its foliage much longer in this highly coloured state. Its red, berry-like fruits also make it more effective. *Gymnocladus canadensis* is represented by a specimen near 50 feet in height, the result of some forty years' growth. Its foliage in form is something like that of the Rose *Acacia* (*Robinia hispida*). There is a fine specimen of the *Diospyros Lotus*, laden with its intensely acid fruit. Near it is *Magnolia auriculata*, said to be the oldest example in the kingdom. *Pyrus hybridis*, supposed to be a hybrid betwixt *Pyrus Aria* and the common mountain Ash, is a fine spreading tree. Here, also, is a grand specimen of the Cork tree (*Quercus Suber*), with a gnarled old bole. An example of *Celtis occidentalis* is said by travellers to have attained a size greater than to be met with in its native habitat. It is a grand tree, its branches very tough in the bark, and pendent at the points. Then again there is the Chinese *Kolreuteria paniculata*, a very distinct tree, its singular seed-vessels in the autumn being like the Horse Chestnut. In general appearance it is not unlike the Kentucky tree, *Gymnocladus canadensis*. *Rhus Cotinus* (the Venetian Sumach), a handsome deciduous shrub, was very effective. It is not nearly so well known as it deserves to be. *Rhus Toxicodendron* (the poison Oak), is a low growing shrub, the leaves of which assume a fine colour in autumn. *Fraxinus quadrangulata*, scarce and distinct, its shoots whilst young having the peculiarity of being quite square. This is said to be very difficult to propagate. *Carpinus americana* (the American Hornbeam) has few rivals for the beauty of the colouring of its autumn foliage. *Morus alba* (the white Mulberry) and its varieties, is said to be the best for silkworm feeding.

The above are some of the most remarkable and distinct trees and shrubs with which this nursery abounds, and which are here to be seen in size and condition such as to be met with in few places. The fashion in trees, as in many other things, seems to run periodically in grooves. For the last thirty or forty years coniferous and taxaceous trees, many possessing doubtful ability to withstand the occasionally severe winters we get, have almost alone found favour with planters, to the exclusion of the more distinct and interesting deciduous trees, the ability of which to stand our severest winters is sufficiently proved, and whose general suitability to occupy prominent positions on lawns, in shrubberies, and in the

dressed grounds, whether comprising hundreds of acres, surrounding the finest mansions, or in the limited space attached to a villa residence, renders them alike worthy of a place. To the lover of trees in general a walk through this nursery with the veteran Mr. Pitman, is a real treat. He has been here some fifty-five years, the greater portion of the time as outdoor foreman. Trees and shrubs of all kinds appear to have been his delight and study. His keen observation and retentive memory are such that the slightest difference in form of leaf, general habit, or any peculiarity which he has seen becomes indelibly fixed in his mind in a way that renders him a most reliable authority.

There is a fine stock of the more generally met with hardy trees and shrubs. A deal of care has been taken in selecting and propagating the best forms and varieties. In Thorns there is great variety, amongst which *Crataegus prunifolia* is a fine red-fruited kind, the foliage in the autumn dying off a beautiful colour; *C. punctata rubra*, the autumn colouring of the leaves of this is the most intense of all; *C. coccinea maxima* is another desirable kind, with large leaves and very large fruit; *C. Aronia* is one of the best of the yellow-fruited kinds. Of Planes, in which Londoners have trees the best suited to their soil and climate, there is here a form under the designation of *Platanus acerifolia pyramidalis*, more compact in growth, and said to be more hardy than the others. After all the discussion there has been about the Oriental and Occidental varieties of Plane, there is one difference yet to be mentioned—the Oriental variety will not strike from cuttings, but the Occidental does; the latter are here all raised in this way. I noticed a new acquisition, *Parrotia persica*, from the shores of the Caspian. In the autumn the leaves, which die off very slowly, are indescribably beautiful, a mixture of vivid crimson and yellow, by the side of which the finest tricolor *Pelargonium* looks pale. Especial attention is paid to Ivy in pots, so useful in giving immediate effect in the covering of walls, &c. All the best kinds are grown, and for freedom of growth are in a condition not often met with. Lilacs for forcing in pots are remarkably well done. *Syringa rothomagensis* is the variety grown. Plants in small pots from 6 to 7 inches were beautifully furnished and profusely set with flower-buds. Another fine forcing plant here is *Viburnum plicatum*.

THE FULHAM OAK.

I have not yet said anything about the noted Fulham Oak (see p. 145). The tree here was for a long time supposed to be the original from the Acorn, and it is said that Loudon had all the soil removed from around the base of the hole to see if anything in its growth could be detected which would confirm or upset this supposition; if so, there was a singular oversight committed, as there is unmistakable evidence of its being a grafted plant, the union being clearly visible in the bark a short distance above the ground. A small sucker from the stock near the ground has sprung up, and so far as the appearance of the leaves go seems to be *Quercus pedunculata*. The spread of the branches covers a space of some 78 feet across; it is supposed to be fully 200 years old, and girths about 15 feet. It has not grown much in height for the last fifty years. In "Murphy's winter," 1837-38, a singular circumstance happened to the tree. During the severe frost that then occurred, one night the men in the bothy at some distance were alarmed by what they thought was a discharge of fire-arms, and ran out-of-doors, when it was discovered to be reports caused by the disruption of the bark through the effects of the intense cold. Something of a similar nature was noticed in several places in the severe winter of 1860-61.

FRUIT TREES.

This nursery has long been famed for its fruit trees of all kinds, which are remarkable not only for their clean, thriving condition, but also for another matter of importance, especially in such things as Peaches and Nectarines, correct nomenclature. Pears particularly are very fine, all or nearly all worked on the free stocks. In giving preference to this over the Quince Mr. Pitman justly observes that all varieties of Pears that are in the least inclined to be gritty are still more so when grafted on the Quince, often to an extent in some soils that makes them worthless.

Amongst kinds not so generally known, or grown in the older established sorts, are *Souvenir du Congrès*, in the way of, but considered superior to *Williams' Bon Chrétien*; *Beurré Superfin*, *Pitmaston Duchesse*,

Beurré d'Amanlis and *Doyenné du Comice*. Apples are likewise grown in very large quantities and are well managed; many are grown on the Paradise stock. Amongst kitchen varieties not much known, but highly recommended, are *Stirling Castle* and *Aitken's No. 2*. Of Plums there is an equally healthy stock: as an early sort nothing is so much in demand as *Rivers' Early Prolific*, bearing profusely in almost any soil or situation; the *Early Orleans* is better liked than the old variety. As a late kind *Belle de Septembre* is coming generally into favour; the Kentish fruit growers are going largely in for this sort, than which no better evidence need be forthcoming. Amongst Peaches there is a great demand for *Stirling Castle*, which is found to do well on most soils; and *Belle Beauce*, an early sort, something in the way of *Grosse Mignonne*, but handsomer, and an immense cropper. *Early Louise* is well liked. Much attention has been paid to the most suitable stocks for Peaches as well as other things. The *Mignonne* or *Brompton* stock is found to be the best for some, as for instance *Stirling Castle*, and the fine, but comparatively little grown late variety *Téton de Venus*; these are here altogether worked on this stock, the former variety absolutely refusing to live on the *Muscel* stock—neither does *Grosse Mignonne* do well on it. In Cherries, the French variety, *Olivet*, a very large kind of the Duke section, and the American Governor Wood, are both recommended as first-rate early sorts. The Portugal Quince is much superior to the old varieties, the fruit larger, and it comes quicker into bearing; it was fruiting freely on three years' worked plants. There is also a fine stock of Peaches, Nectarines, Plums and Pears in pots.

GLASS DEPARTMENT.

The show house is a long span-roofed structure containing the usual fine-leaved and flowering subjects; I noticed here a fine stock of *Ficus lanceolata*, an excellent plant for living rooms, and which can be used in place of the *Ficus elastica*, requiring like treatment: the leaves are deep-green and shining like those of the latter variety, but are much more elegant in shape. Palms, *Dracenas*, variegated *Phormiums*, *Cordylines* and *Yuccas* are here grown—amongst the latter are several fine specimens of *Y. filamentosa variegata*; with these are associated a quantity of Ferns. On the roof are grown the rose-coloured *Lapageria* and *Clematis indivisa*.

Adjoining this house is a long hip-roofed range in four divisions, the first of which was filled with young Palms, consisting of most of the popular kinds. In the next house I met with an old plant, long in the country, but with many now lost sight of, *Murraya exotica*, an erect growing hard-wooded subject with white flowers, in character like a cluster of small Jasmine flowers, and highly fragrant; the perfume may be described as something betwixt Jasmine and Orange blossom.

The two remaining houses are used as general stoves, in which were a number of specimen foliage plants, comprising different varieties of *Pandanus*, *Palms*, *Caladiums*, a very fine example of *Cycas circinalis*, mixed with smaller things, such as *Aralias*, *Reedia glaucescens*, the Fern-leaved *Campsidium*, most of the newer *Crotons*, the handsome-leaved *Terminalia elegans*, a number of young plants of *Cocos Weddelliana*, and some nice specimens of variegated Pine-apple, intensely coloured, much shorter and stouter in the leaves than usually seen. Thus grown, it is one of the handsomest coloured leaved plants we possess.

At a short distance are several span-roofed houses filled with greenhouse plants; the first was occupied by a quantity of the tender kinds of *Rhododendrons*, *Daphne indica*, *Lapagerias*, and an assortment of the best sorts of greenhouse climbers.

Another was devoted to *Camellias*, mostly traded plants in healthy condition.

In another house were most of the leading kinds of *Dracenas*, *Gardenias*, and the useful *Brunfelsia americana*, with its long tube-shaped flowers; *Epiphyllums*, *Ardisia crenulata*, raised from seed; *Bouvardias*, seedling *Palms*, and *Eucharis amazonica*.

In the propagating house the usual work of striking and grafting was going on; the newer and finer leaved varieties of *Aralia*, such as *A. Veitchii*, are found to do remarkably well grafted on *A. Guilfoylei*. I noticed here a handsome seedling *Dracena*, with drooping leaves, and habit something like *D. Mooreana*, bright green, banded and edged with white and pink.

A long house was filled with Figs in pots, consisting of the best kinds. There is a roomy span-roofed house devoted to young Vines for planting,

comprising the older-established kinds, as well as new ones. Amongst those which made their appearance some years back, and were by many people discarded before their qualities were fully proved, are Madresfield Court and Mrs. Pince's Muscat, which are again in much request.

Another very large double span-roofed house was filled with a grand lot of fruiting Vines, than which nothing could possibly be finer, taking into account both size and general condition. Very great pains are here taken to obviate that (to gardeners) most provoking disappointment—Vines purchased for fruiting, and having no fruit in them. They are trained near the glass, and kept in the house until the leaves have either fallen or are quite yellow, the effect of which is very different from that which results from turning out-of-doors whilst both wood and foliage is in a half-ripened state. Amongst the new kinds, Golden Queen appears to be a very strong grower.

The general nursery stock was in fine healthy condition, evincing careful attention. In the outdoor department plants of all kinds gave unmistakable evidence of the periodical removal so essential to their well-doing when planted where they are to be permanently grown. *Zed.*

NEW VEGETABLES.

THE following memoranda on certain new vegetables which have been grown here may be useful to many growers, affording them information on a point on which they may have had no opportunity of acquiring more direct information:—

Pea Sutton's Dwarf Wrinkled.—Height 12 inches; very early and useful.

Pea Laxton's Standard (from Veitch).—A grand second early; height 2 feet 6 inches, full of well-filled pods, splendid flavour; must be in every one's garden.

Pea Sutton's Tall Wrinkled.—One of the best main crop Peas I ever saw; height 4 feet, a good cropper; all the pods well-filled. In flavour equal to Veitch's Perfection. Here we have a Pea which has long been sought after.

Pea Carter's No. 100.—A second early, a good cropper, and the Peas of a good colour, but not quite so sweet as in some varieties; very prolific in pod.

Radishes, Carter's New Scarlet and White Turnip.—Both splendid in flesh and flavour; clear as crystal in skin and colour.

Of *Sutton's Lettuces* there is only one really good Brown Cos. Is this the one that was sent out in 1869 as Moor Park? If not, it is quite new and very first-class, holding good when other varieties have all gone to seed. *C. Penny, Sandringham, July 28.*

THE PHALÆNOPSIS HOUSE AT BROOMFIELD.

ONE seldom meets with a floral scene more enchanting than that presented by the bank of blossoms in Mr. Warner's Phalænopsis-house, when the plants are in the height of their bloom, as represented in the accompanying engraving (fig. 28), from a photograph. The number of plants here collected together and forming one grand group, is unusual; their health and vigour has been seldom equalled, and perhaps never surpassed, and the variety in the form and colour of the flowers is quite charming. Here might be seen in the early spring season, in the full glory of a profuse inflorescence, the well-known forms of *P. amabilis* and *grandiflora*, laden with their grand panicles of broad massive milk-white flowers, and forming a striking contrast to the various lovely shades of rosy hue presented by the floral panicles of *P. Schilleriana*; while the mottled leaves of the latter mingled with the clear green foliage of the older kinds, came in as a most effective base and background, giving to the mere colour-effect a richness and softness of which it would be difficult to find a parallel. To the Orchid grower and to those who are at all familiar with Orchids, the healthy vigour of the plants, and the strength of their grandly paniced inflorescence, would prove even a greater charm, so exceptional is it to see such a rich assemblage of these rare and valuable specimens so well managed as in this case. Mr. Warner has, indeed, had long experience in Orchid growing, and he has turned his experience to good account, as the view we now publish will abundantly testify.

With trees and shrubs and flowers in the outdoor garden there can be no question that the massing principle is far more effective than the promiscuous dotting about of even fine individual specimens; and

it is the same with the inmates of our glasshouses, as witness the Odontoglossum-house at Trentham, the Masdevallia-house at Messrs. Veitch's, the Cattleya-house at Broomfield, and again, in its season, the splendid bank of Phalænopsis which has occasioned these remarks. The distinctive characters of the plants are, in such cases, strengthened by iteration, and the consequence is that a much more impressive effect is realised. Even when the collection is less extensive than in this case, and when consequently a separate structure cannot be afforded to the different family groups, we strongly recommend the system of grouping the plants, rather than that of intermingling them promiscuously. This mode of arrangement is not alone more pleasing in the effect produced, but is obviously advantageous in studying and carrying out the cultural requirements of the plants themselves.

The general treatment to which Mr. Warner's plants are subjected, and by means of which he keeps them in such a satisfactory condition, has been so often alluded to in our pages that we need not now enlarge on that point, and we will therefore only further say to those who doubt the advantages of the grouping system, look on this picture and be convinced. We add a few further remarks, communicated by Mr. B. S. Williams, by whom the plants were also inspected when in flower:—

"The Phalænopsis-house of R. Warner, Esq., Broomfield, Chelmsford, presented at the end of February last an Orchidaceous spectacle especially grand. The view of a house principally filled with these charming Orchids when in their full beauty, cannot fail to leave a lasting impression. The house now referred to is more than 50 feet long, and on either side was a fine display of the charmingly graceful drooping and arching spikes of mauve and white flowers, intermixed with other fine Orchids of different colours. At the time of our visit there were many hundred blossoms, and so it is every season; in fact, it has been our pleasure to witness this display each season for the past fifteen years. Many plants of Phalænopsis Schilleriana had fifty or more flowers upon them, and they were in vigorous health and with good firm foliage. This may be accounted for by their not being grown in too much heat. Some Orchid growers persist in giving them more heat than they require, but Mr. Warner has always grown them in a good-sized house, with a free circulation of air during the summer months, and with less heat in winter than most growers give them. We cannot doubt but that this is the right plan, as they were growing stout and strong in foliage, and producing fine spikes of flowers, which continued a long time in bloom. *P. grandiflora* and *P. amabilis* are cultivated in the same house as *P. Schilleriana*, and continue flowering from February until April. They are extremely useful for bouquets, cut flowers, &c., and what more graceful or charming can be found than a spike of *P. grandiflora* or *amabilis* for the decoration of a lady's hair?—it is not only most lovely but lasts long, as if carefully preserved in water the same spike will serve for several times.

We have said how well the plants are flowered, but besides this Mr. Warner has collected the most distinct varieties as to form and colour. The true mauve of the Schilleriana combines well with the white of *grandiflora* and *amabilis*, and the foliage of other Orchids amidst their lovely spikes of aerial beauty also conduces to the effect produced. This all lends a charm to the scene, the impressive effect of which can be fully realised, as one may stand at the end of the house and see every spike to advantage.

The Odontoglossum-house was also in good bloom. The many varieties of *O. Alexandræ* and *O. Pescatorei*, with their splendid spikes in full perfection, and intermixed with the bright colours of *O. triumphans* and *O. luteo-purpureum*, and the creamy white and spotted flowers of the *O. Andersooiaum*, made a charming contrast. There were many of the bright coloured Masdevallias in bloom, the magenta and scarlet hues of which had a pretty effect amongst the various white flowers of the Odontoglossums. *B. S. W.*"

THE ROYAL GARDENS, KEW.

(Continued from p. 108.)

CHARCOAL FOR GUNPOWDER.—The large consumption of Dogwood for this purpose of late years in Europe has produced a scarcity of this material. The Royal gunpowder factory at Waltham Abbey appears to have drawn its supplies of *Rhamnus Frangula* wood from Germany, though it might be grown in England on the coppice system with the greatest ease. A substitute has, however, been proposed for it, and a specimen of the wood was sent to Kew for identification. It was determined to be Hornbeam (*Carpinus Betulus*), which has been, at any rate, formerly employed for gunpowder manufacture at Berne.

CHICLE GUM.—A protracted correspondence has been carried on with the Colonial and Foreign Offices with reference to a gum known in New York (where it was used for chewing) under the above name, which it was supposed might be valuable for telegraphic purposes. It was confused in some way with another very obscure product known as Monesia, which is used in medicine, and which appears to be derived from the Brazilian *Lucuma glycyphlæum*. Chicle gum, on the other hand, comes from Mexico, and is produced, according to our most recent information, by *Achras Sapota*. A specimen sent to Kew was submitted to Messrs. Siemens Brothers, and they reported that in "mixing with india-rubber it made the latter too brittle, and therefore cannot improve the quality of the rubber if intended for the insulation of cable wires."

"COCOA-NUT DISEASE" OF DEMERARA.—Great destruction has been wrought in the cocals of Demerara by the larvæ of a small beetle (*Passalus tridens*) which completely destroy the soft tissues of the interior of the stems, and eventually of course inevitably kill the trees. It is difficult to prescribe any remedy except "stamping out" by burning the infected trees as soon as they show symptoms of the larvæ being at work.

COFFEE DISEASE.—In my last report I stated that Dr. Thwaites, the Director of the Botanic Gardens, Peradeniya, Ceylon, had drawn up a series of questions on this subject which have been addressed to the various Coffee-growing countries and colonies. All the replies and information that are likely to be received in answer to this enquiry having now come to hand, I have thought it would be most useful to summarise the results in the present report as likely to give them the widest circulation.

According to the replies no disease, or at any rate none with the characteristic peculiarities of the Hemileia, occurs in any of the following seats of Coffee cultivation:—Angola, Bahia, Bermuda, Cartha, gena, Cayenne, Costa Rica, Grenada, Gold Coast-Guiana (British), Jamaica, Java, Madeira, Mauritius, Nicaragua, Réunion, St. Helena, Sierra Leone, Trinidad.

In the following places from which replies have been sent Coffee is not grown:—Barbadoes, Buenos Ayres, Honduras (British), Leeward Islands (except Dominica), St. Vincent, Surinam, Zanzibar. With respect to the remainder, the information received may be conveniently summed up under the following heads:—1. *Hemileia vastatrix* ("leaf blight") of Ceylon and Southern India and associated diseases. 2. *Cemistostoma coffeellum* ("Coffee fly") of the Antilles and Brazil and associated diseases. 3. "Borer." 4. "Coffee-bug." 5. "Canker" and other vague diseases attributable to climatic causes.

The reports received bearing on these several heads are perhaps not as complete in information as might have been both expected and desired.

In the light, however, of knowledge derived from other sources they have proved to possess considerable interest. In some cases the statements have been of a very hypothetical nature, as, to give one instance, where a South American reporter expresses the opinion that the Ceylon disease—the vegetable origin of which is unequivocally known—is "propagated by myriads of diminutive insects."

I cannot refrain from calling particular attention to the fact that whereas in British Guiana Coffee was once largely cultivated, especially in the county of Berbice, it is now "imported."

1. *Hemileia vastatrix*.—The "leaf disease" is a scourge of quite recent origin. In May, 1869, a few Coffee plants were noticed in Ceylon to be attacked by a fungus upon the leaves. In July following 2 or 3 acres of Coffee plant were found to show it. After this its progress was quite extraordinary, and in 1872 it was to be found in nearly all, if not all, the estates in the island. It also soon spread to Southern India, and though Java is at present free from it, I learn while this report is in preparation that it has made its appearance in Sumatra. I have, however, found no satisfactory evidence of its existence in other parts of the world than the islands and countries contiguous to the Indian Ocean. I conclude, therefore, that it is at present a local or endemic parasite, which, however, unless measures are taken to prevent the introduction of Coffee plants from infected countries into others at present free from it, may be expected to spread eventually wherever Coffee is cultivated. The fungus, which is allied to the Moulds, was first described by our distinguished English fungologist, the

Rev. M. J. Berkeley, in the *Gardeners' Chronicle* for 1869 (p. 1157, with a woodcut), and subsequently in the *Journal of the Linnean Society (Botany)*, vol. xiv., p. 93, pl. 3, fig. 10). A short account also appeared in the *Quarterly Journal of Microscopical Science*, 1873, pp. 79-81. It is probably indigenous to Ceylon, and has only assumed the proportions of a scourge because it has found the constitution of the Coffee plant suited to it.

The conditions under which the economic plants are grown in large areas are, of course, extremely favourable for the rapid extension and development of parasitic plants and insects. When these have only native plants in small quantities to prey upon they pass unnoticed, and their appearance on a large scale is one of the penalties which man must expect to pay

co-operation of the Rev. R. Abbay, Fellow of Wadham College, Oxford, who was attached to the Eclipse Expedition, and remained some time afterwards in Ceylon for the benefit of his health. Mr. Abbay's observations, though imperfect, are a first step towards a more accurate knowledge of the subject, and will, I hope, shortly be published.

The mycelium, or vegetative part, of the *Hemileia* penetrates the tissues of the leaves of the Coffee plant, where it is out of the reach of any agent such as sulphur (whether applied in powder, as is so successfully done with Hop mildew, or, as suggested by Mr. George Wall, by fumigation). Moreover, the detailed treatment of the trees in a large plantation by any remedy of the kind would be practically impossible. I fear that the "leaf disease" is a

(*Gardeners' Chronicle*, 1876, February 19, p. 246; March 4, p. 308; *Grevilla*, 1876, vol. iv., pp. 116, 134-135). From a report by Dr. Cooke, issued by the India Office, it appears that the *Pellicularia* "makes its appearance about July, when the leaves of the trees affected by it get covered with a slimy gelatinous matter, and, turning black, drop off; the berries likewise rot and fall in clusters." It is estimated that nearly one quarter of the crop each year is lost by this plague. The collection and burning of the dead leaves will in this case also have to be persevered with. As suggested by Dr. Cooke, the fungus being external in its growth, is likely to be materially checked by the application of sulphur.

A somewhat similar disease to the *Pellicularia*, but described in too vague a manner to speak definitely

FIG. 28.—MR. WARNER'S PHALÆNOPSIS HOUSE.

for such an enormous disturbance of natural conditions as is implied in replacing a tropical forest of the most varied and mixed vegetation by a plantation of some single economic plant. In temperate countries exactly similar phenomena are exhibited by the rapid spread of the Potato fungus, the Vine louse (*Phylloxera*), and the Potato beetle from the western side of America, first to the eastern, and then, at any rate in the case of the two former, and no doubt eventually in the case of the latter, to the Old World.

Mr. Berkeley's examination of the *Hemileia* was made from dried Coffee leaves transmitted to this country. A first essential is a more adequate study of the fungus than such specimens could afford, especially in all the details of its life history, from germination to fructification. Some progress in this latter task has been made by Dr. Thwaites, with the

trouble with which the planters for the future will have always to reckon. As with our own Potato disease, they must rest their hopes on the likelihood of its proving intermittent, and bear, as best they may, the constant loss of a certain percentage in every year, with occasionally the loss of an entire crop. At the same time every precaution should be made to destroy all the infected leaves by burning, and, even when more certain knowledge is arrived at, to boldly sacrifice the foliage of trees on the first symptoms of the malady, so as to prevent the fungus ripening a fresh crop of spores.

In Mysore another disease appears also to be rather prevalent, which is produced by a fungus distinct from the *Hemileia*. This is known as the "leaf-rot," or *Kole-roga*. It has been described by Dr. M. C. Cooke under the name of *Pellicularia kole-roga*

upon, seems to have occurred in 1864 in Jamaica, the leaves of the Coffee plants being covered "with a white substance of a glutinous nature."

As I have stated in an earlier portion of this report, the Liberian Coffee has not proved exempt from the attacks of the *Hemileia* in India and Ceylon. Mr. G. A. Cruwell, who has visited Liberia, believes that it is affected with the *Hemileia* in its native country. Specimens sent to Kew by him are pronounced by Mr. Berkeley not to be affected by the Ceylon leaf disease, but to owe their discoloration to some other cause.

2. *Cemistoma coffeellum*.—A disease has for many years been known to exist in the Island of Dominica, and also to a large extent in Brazil. This was characterised by the appearance of large discoloured blotches upon the leaves, leading eventually to their

decay and fall, and so seriously impairing the health of the trees. The leaves are destroyed by the larvæ of a minute but very prolific moth. They live between the two surfaces of the leaves, and gradually consume the intermediate cellular tissues. The moth is, in fact, a member of the same genus as that which mines the leaves of the Laburnum in our gardens. This insect is said to lessen the Coffee crop in Brazil by at least one fifth. The little pest has been found in the Antilles, Island of Martinique, province of Rio Janeiro, and over the whole Coffee region of Brazil.

According to an enclosure in Mr. Acting Consul Austin's despatch to the Foreign Office, it is of comparatively recent introduction into Brazil:—"In 1854, or soon after, the Imperial Government, desirous of introducing several species of Coffee amongst us, advantageously cultivated in other parts of the world, committed the error of importing plants instead of seeds, and thus we had here Coffee trees grown in Ceylon, Martinique, Bourbon, &c., it being quite possible that in this manner the germ of the Coffee disease was imported." This is also the opinion of Mr. B. Pickman Mann, who has reported in the most admirable manner upon the whole subject to the Brazilian Government (see *American Naturalist*, 1872, June and July). I may also call attention to a similar transference, from the Old to the New World, of the moth which injures the Sugar-cane, and which is referred to below. The only plan of radically dealing with this pest is to destroy the injured leaves while the Coffee-fly is still in the larval state. Mr. Mann remarks:—"If the leaves were picked at such a time as to take the greatest number of larvæ when they were about two weeks old, it would not be difficult to select them, as the size of the blotches would make them very noticeable. I find that the expense would be more than met by the next year's crop."

Mr. Consul Pauli has sent from Puerto Rico leaves which are affected with the *Cemiotoma* in its most characteristic manner. The disease appears to do little injury in this island, and no particular attention is paid to it.

In Venezuela a disease occurs which is known by the name of "candelillo," and which is also, according to the information supplied by Mr. R. T. C. Middleton, Her Majesty's Minister at Caracas, identical with the "mancha de hierro," or "iron-stain." Dr. Ernst, however, believes them to be different, and attributes the latter to the *Cemiotoma*. The specimens forwarded to this country by Mr. Middleton of the iron-stain are, however, at once distinguishable from the ravages of the *Cemiotoma*. The leaves have been submitted to the Rev. M. J. Berkeley, who reports that they are affected by a minute fungus, a *Depazea*, for which he proposes the specific name of *maculosa*. It has fusiform spores, .0008 inch long, and containing about seven nuclei. In Venezuela Coffee appears to suffer little, comparatively speaking, from maladies of any kind.

3. "*Borer*."—In all tropical countries trees of all kinds (the Cocoa-nut Palm mentioned above is an additional example) are peculiarly liable to the ravages of various wood-eating beetles. Coffee is no exception, and the reports from various countries mention "borers," no doubt different in every case, with which the cultivator has to contend. They are peculiarly met with where the plantations are new clearings, and an important means of extirpating them is the systematic clearance of any decaying or other wood which they can use as a refuge.

They are mentioned from the West Coast of Africa, Sierra Leone, Liberia, and Gold Coast; they are also occasionally troublesome in Jamaica. It is in South India, however, that they work harm on the largest scale, and for an account of the *Xylotrechus quadripes*, which is the "borer" of that country, I must refer to Dr. Bidie's report on its ravages, published in 1869.

4. "*Coffee Bug*."—While "borers" attack the roots and stems of Coffee trees in hot countries, various species of *Coccidæ* suck the juices of the young twigs and leaves. Under the names of "blight," "bug," and "scale," these are mentioned in the reports from Gold Coast, Hawaii, Madeira, and Trinidad. In the latter case they are noted as being accompanied (as is often the case when they attack the Orange), by "sooty-blight," a fungus (*Capnodium*, sp.), which covers the leaves with a dark incrustation. The Coffee-bug of Ceylon (*Lecanium Coffeeæ*), was once a source of considerable injury to the Coffee estates of that island. It is described in Emerson Tennent's *Natural History of Ceylon*, pp.

436-441. As in other countries, in the face of careful cultivation it appears to have ceased to give annoyance.

5. "*Canker*."—Coffee, for some imperfectly understood reason, has apparently failed to hold its ground in Natal. It is subject to a "bark disease," which is thus described by Mr. C. T. Sauer:—"The first symptom of the disease is the withering of a small tertiary or secondary branch; on further examination it will be found that the bark, under the primary branches, is decayed and blue-mouldy; the blue mould extends downwards gradually over the whole stem, killing the tree in a few months. . . . A tree once attacked never recovers. . . . All soils and situations seem alike liable to the disease; the trees seem to begin to suffer when about six years old. The area of land under Coffee has been already much reduced, the crop having already proved unremunerative; the Sugar-cane is gradually but surely supplanting the Coffee tree."

Here, of course, the mould is the proximate cause of death, but the ultimate cause is evidently, from the fact of its appearing when the trees are at the age of six years, due to some unfavourable external condition. The opinion of experienced persons in the colony is so entirely at variance as to what these may be that I am indisposed to express any myself. The collapse of Coffee growing is by some attributed to neglect of cultivation, by others to unsuitability of climate, and last of all to want of depth of subsoil, as shown by the small height attained by the native arboreal vegetation.

In Jamaica "canker" is also spoken of as a source of constant loss of about 1 per cent. per annum of the Coffee trees. Its effects increase with age, and are attributed to the roots penetrating to uncongenial soil. Local "blights" also occur, which are attributed to sudden climatic changes.

In Java a fungus attacks the trunks, giving them "a white appearance," and produces death in all the parts above.

To be continued.

Apiary.

DO BEES MASSACRE THE DRONES.—I don't think Mr. Murray's suggestion in your last issue very fair in regard to finding out whether the bees really massacre the drones or not. Shutting them up in a hive for a month would be certain death to most of them, and would in no way settle the question. Before I read Mr. Murray's notice I was watching daily all their movements most carefully to see what was their intentions towards Mr. Drone after he was required no longer, and I am more convinced than ever that they persecute him to death. When I lift a skep at any time now, they have all the drones banished on to the floor-board, and in several cases I have found in the morning a great number of drones lying before the skeps, which must have been pulled out of the cells for they never were the length of flying. In my apiary just now a great many of the skeps have begun the drone war, that is, every drone is seized as he goes out or in and is put overboard if possible. As I said before, I don't think they ever attempt to use their sting, but I have seen repeatedly the bees pinching eagerly at the juncture of the wing, and very often after they are overboard they are never able to fly again, but otherwise seem all right as they are quite able to run about. For one should never believe the question settled by shutting the drones up till they died. *W. K.*

Foreign Correspondence.

THE COLORADO BEETLE.—Thinking your readers would like some account of these interesting insects, which have become of late the all-absorbing topic and occupation of the Potato growers in Canada, it may not be amiss to give you some particulars, in all probability not generally known in your part; and first, with regard to their appearance, they are dressed so elegantly and appropriately that it seems quite a pity to kill such beautiful creatures, so finely proportioned and painted with alternate stripes of highly burnished dark and light chocolate, and their shoulders spotted in like manner and finished off with elegant heads and horns. They fly very prettily, and without any undue haste, and have an unerring scent for any small patch of Potatoes, even if only the remains of the previous year's crop come up amongst

other vegetables; they gather about the plants as soon as they appear, and proceed to devour the leaves as they unfold themselves, and at night nestle around the earth at the roots for shelter. In a few weeks they pair, and lay patches of brilliant yellow eggs about thirty to sixty each in number, from which minute grubs issue, grow rapidly, and attack the poor esculent with unremitting vigour, soon leaving a field of bare poles as the sole reward of the careless planter; but as this result does not approve itself to most of us the question is, how to destroy this pest most successfully, and some use Paris-green mixed with flour, others in water, which seems the best plan if all the animal life of the field is to be destroyed; but those who prefer leaving Nature to provide some enemy eventually to extirpate our foe daily pick all the beetles and eggs visible, and so, after many weeks of labour, obtain a fair crop of delicious Early Rose—the sort now universally grown in this locality, but still not in the quantity we used to dig before the Colorados made their unwelcome appearance. It is very curious in picking to notice the instinct of both beetles and eggs of all ages, which, as soon as disturbed, practise what is called "the opossum trick," viz., fall down apparently dead, instead of taking to their wings and flying away, as a much smaller and less handsome variety invariably does; but we leave this insect unmolested, as we believe it feeds on the eggs of the larger one, although not to any very appreciable extent at present. Recently, however, we have seen two enemies devouring the eggs, viz., a small round black beetle and a very minute fly of the same colour; and it is said that in some districts a large black insect is attacking when at maturity these annoying adversaries to our daily dinner-table. The Potato-beetle has been known after finishing the Potatoes to attack the Tomatoes. It mostly lays its eggs on the south or south-easterly side of the plant, but also sometimes on Thistles or grass. The price of Potatoes has been very high of late, in consequence of the labour connected with their growth, and ranged from 80 cents to 1 dollar the bushel of 60 lb. in Barrie.

In conclusion, you may be congratulated you have no beetles in addition to the many diseases Potatoes seem to be heir to in England; but some of us seem to think it is a pity that you, who have so much time and labour to spare [!] have not the Colorados instead of us, to whom time and labour are so rare and valuable. *John Morren, Elm Farm, Minsing, Canada, July 14.*

P.S. By-the-bye, we have an extremely beautiful spider, which has apparently come with the beetles; it has a very stout pale yellow body, with a dark chocolate-coloured head. For the information of apiarians, as to the capabilities of this country for their craft, I may state the result of one day and a-half of the work of fifteen hives last week in this neighbourhood, amounting to 150 lb. of brilliant, excellently flavoured honey. Could any of your readers favour us with the proper temperature for a winter bee-house, as we are much puzzled at our climatic variations and the number of deaths frequently occurring in consequence?

Garden Operations.

PLANT HOUSES.

GREENHOUSE HARD-WOODED PLANTS.—Now that a considerable portion of the specimen and half-specimen hard-wooded plants are removed to the open air, an opportunity will be afforded of allowing more room for the smaller young stock which, often for want of space in the early part of the season, are let to stand too close; and although this at any time of the year, but especially while the growth is being made, should never be permitted; yet, where there has been any overcrowding, it will to some extent improve the condition of the plants by, from this time forward through the autumn, standing them sufficiently far apart in a light house. Any further tying-out or training required should at once be attended to, for whilst yet growing, the leaves and points of the shoots will assume their right position, a circumstance that will not occur later on when the growth is finished and the wood become hardened. Be careful to keep the strongest shoots tied down the lowest, leaving the weaker growths free to assume an erect position, by which means the future growth will be much better equalised than by any possible amount of stopping the strong shoots, though in most instances it will be necessary to pinch out the extreme points of the latter. All hard-wooded

plants that are subject to the attacks of red-spider, should during the summer be looked carefully over every fortnight or three weeks; where such precaution is not taken this insidious little insect, which in hot weather increases so rapidly, often does irreparable mischief, especially to young plants, before it is detected. Whenever young growing stock gets infested with it to such an extent as to injure or prematurely destroy a portion of the leaves, it induces a hard stunted condition of the wood that seriously affects the capabilities of the plants for free development in future. Through this many beginners in the cultivation of these subjects fail, although the cause is often attributed to some deficiency in the soil in which they are grown, or defective cultural treatment in other matters. Where spider has got established to any considerable extent the simplest, cheapest, and best remedy will be either dipping in or syringing with a weak solution of Gishurst, 2 or 3 oz. to the gallon. Such things as Chorozeas, Gompholobiums, Polygalas, and Pimeleas, where the intention is to grow them well, should be syringed overhead with clean water daily all through the growing season—not being content with sprinkling the tops of the leaves with a dash from the syringe, which has little or no effect upon the insects, as they lie secure underneath, but getting the water to the under surface, and wetting the foliage all round. During this month the atmosphere of the house may be allowed to get a little drier than early in the season, so as to gradually harden up the shoots and leaves, and except in the case of any plants that are late in making growth, and which ought to be kept separate from the general stock, air should now be left on all night, not closing the house in the afternoon. The humid condition of the external atmosphere, consequent on the recent showery weather in most parts of the country, will have just suited the larger plants that are now fully exposed to the open air, and to some extent will have relieved the necessity for daily syringing overhead, yet when the weather is at all dry there must be no lack of attention in this matter, in addition to which the whole must be carefully looked to every day as to the water requirements of the soil. The latest flowered Epacris that have been kept under glass to induce them to make growth may be turned out about the middle of the month, as three weeks' exposure will in most cases be found sufficient to induce them to set their flower-buds just as well as a longer period out. Hedaroma (Darwinia) tulipiferum requires especial treatment. If the plants are turned out-of-doors before its flowers are set, which is easily seen by the points of the shoots turning down in a hooked fashion, it will very rarely set at all. I never saw an instance of a plant blooming freely that was exposed to the open air previous to the flower-buds being thus formed, and yet there is no plant grown that it is more necessary to submit to open-air exposure for a few weeks, as when kept under glass all summer the leaves and points of the young shoots never get enough hardened to resist the attacks of mildew; but neither it nor the smaller species, *H. fuchsoides*, should ever be stood where they are under the full influence of the mid-day sun, or the foliage suffers. The best position I have found for these plants when out-of-doors is at the north side of a moderate-sized tree, sufficiently far from it to just avoid the drip, but where they will be sheltered from the sun's rays for four or five hours during the middle of the day.

SOFT-WOODED GREENHOUSE PLANTS.—Large-flowered Pelargoniums that were recently turned out-of-doors to ripen their wood should at once be cut down, otherwise there will not be time for them to make growth and to get the potting completed in due season. The fancy varieties must not be cut in nearly so close as the large-flowered kinds. If the plants at the time of cutting down are at all affected with aphides the shoots should be fumigated or washed with tobacco water (the latter is more effectual, as it not only destroys the mature insects, but also their eggs), or the insects will attack the young growth as soon as they break, in which way they will do serious harm by checking the first efforts the plants make. Before heading down see that the soil is in a moderately dry state, and that it does not receive much water until they have again got fairly into growth. On cutting the plants back immediately put them in a cold pit or frame to induce them to break, to assist which damp overhead daily with the syringe. Small plants struck in the spring of both large-flowered and fancy kinds should have their points stopped and the shoots tied down in a horizontal position, almost level with the rims of the pots. It is essential that they be thus shaped whilst young, otherwise these Pelargoniums can never afterwards be got into the requisite form, as, even for ordinary decorative purposes, they are very unsightly when the growth is allowed to run straight up in an erect position. Chrysanthemums now in their blooming pots should be tied so as to prevent their being broken with the wind, and from this time forward should be liberally and continuously supplied with manure-water. Syringe them overhead with clean water every evening; this, with abundant root

moisture is essential, not only to the production of the full complement of fine flowers, but it is also necessary to preserve the lower leaves in a healthy growing condition, without which, even if freely bloomed, they have an unsightly look. *T. Baines.*

FRUIT HOUSES.

PINES.—We amongst others engaged in the cultivation of these which have to furnish a supply of ripe fruit annually for the London season, have necessarily to devote special attention to the subject. We find the Queen variety pre-eminently the best suited for the purpose. At about this season the suckers obtained from the current year's fruiting plants will be rooted. We divide these plants into two sections; the first of these comprises the strongest and most forward plants: these when they are properly rooted are placed into 10 and 11-inch fruiting-pots, and replunged into a bed having a temperature of about 95° where the base of the pot rests, and have every encouragement afforded them to make vigorous growth during the remainder of the growing period. The second section of these plants includes the smaller ones, which are reotted when they are ready for it, into 8-inch pots, in which they remain until the subsequent spring, when they are likewise placed in fruiting-pots of similar dimensions to those referred to above. These plants have only a temperate course of treatment, so as to keep them steadily advancing. The first selection of plants started with us identically last year, have now completed a growth, and are in a fit state for hardening by means of ventilation, preparatory to being excited to throw fruit for the early part of next summer, and the second portion being now in full growth, which will form a successional supply. Timely attention should be given to the state of the soil which will be required for potting, as at this season it is apt to become too dry. Prepared soil should also be well covered up to avoid the consequence. This and the following month is undoubtedly the prime period in the whole year for these subjects. *George Thos. Miles, Wycombe Abbey.*

VINES.—Where early forcing is contemplated the wood should now be approaching ripeness. A dry warm atmosphere by day, with plenty of air at night, will most likely bring about conditions favourable to the production of close compact bunches, which always set and colour better than those which are borne by half-ripened wood. Pot Vines now ripe may be removed to a sheltered sunny situation out-of-doors for a time. Let them be well secured from injury by wind, and protect the roots from drought by a good covering of dry Fern or litter. If at this season it is necessary to keep back Grapes for any length of time after they are ripe, a little light shade drawn over the roof for a few hours on bright days will greatly aid in preserving the colour, but the wood and foliage should have the benefit of full exposure to light when the sun is off the house. Muscats still green, also Lady Downe's, Alicante, and other winter kinds, this year later than usual, should have the benefit of a warm temperature to secure perfect maturation of fruit and wood by the end of September, as fruit ripened after that time generally shrinks and keeps badly when transferred to bottles in the Grape-room. Observe former directions with regard to scalding, and see that the night temperature does not fall below 70°, with a little air at the top of the house, which must be liberally increased as the day temperature rises. Young Vines planted out this spring which have not filled the space allotted to them should still have abundance of heat and moisture. Stop all laterals from the base up to the pruning bud, and let the remainder have full play over the trellis. Early Vines which have not finished satisfactorily may now have the inside or outside borders removed and replaced with new compost without detriment to next year's crop. The house should be kept close, warm, and moist until new root and lateral growth sets in. *W. Coleman.*

MELONS.—Lose no time in getting out the latest sowing of Melons as soon as they are strong enough for removal to the fruiting pots. If the house is well supplied with pipes for top and bottom heat when the nights become long and cold, good fruit may be obtained; but without these appliances a satisfactory result is very uncertain. Give abundance of tepid liquid to plants swelling off fruit as the growth at this season is rapid, and syringe freely when the house is closed in the afternoon, but avoid wetting the foliage of delicate kinds subject to scalding at the morning syringes. While giving liberal ventilation with decreasing supplies of water to plants ripening or approaching that stage carefully guard against sudden checks. Many crops of fine Melons have been prematurely ripened by the sudden change from a moist genial growing atmosphere to one of sterility and starvation. Plants in pits and frames will require all the attention that can be given to them if success is to be certain, as nights are still cold, and a little more sunshine would be an advantage. Keep the foliage the reverse of crowded, but at the same time let the frame

be well filled with leaves. Stop all laterals, long or short as the case may be, until all the space is filled, as Melons like Grapes are sure to finish well if they can be kept in healthy growth. If manure is used for mulching be careful to use that which is free from worms and avoid placing it close to the stems, particularly where the plants are subject to canker. The best and safest top-dressing at all times and in all places is a good layer of heavy loam well charged with done-dust, and all extra food can be supplied at the right time in the form of liquid manure. *W. Coleman.*

KITCHEN GARDEN.

All good cultivators will now be able to rejoice in having followed up a systematic course of trenching up the soil deeply. At no season does the benefit to be derived from the practice give more certain evidence of its efficacy. All crops which have been planted in soil which has, say, within the last twelve months been moved deeply have the greatest possible advantage over such as are planted in ground which has been, perhaps, for some years merely dug over. They lay hold of the soil at once, and start away, let the weather be ever so hot and drizzly. One good watering generally suffices to give them a fair start, and all the after-care required is to keep the surface-soil well pulverised, both to retain the moisture and keep down weeds. This is an operation which must be persistently carried on amongst all crops advancing forwards for autumn, winter, and spring use. If any of these are still left unplanted no time should be lost, but especially see to the stock of Walcheren Cauliflower. This is one of the most useful and delicate of autumn vegetables, and deserves liberal treatment both as to enrichment of the soil by manure and copious supplies of liquid manure and water alternately. Veitch's Autumn Giant Cauliflower also deserves very liberal treatment; the first sowing will soon begin to furnish sound, compact heads of a fair size, and is more certain than Cauliflower; but experience proves that there should be at least three successional sowings at intervals, and the same with planting, in order to keep up a succession of decent heads, as it is very apt to come in all at once, and thus is soon over. Early sorts of Potatoes will now be generally ready for lifting, and advantage should be taken of this at once to clear a large space, to be at once sown with Turnips for the autumn and winter supply. The sorts may consist of one-half Snowball and the other Veitch's Red Globe, which is a very hardy and valuable variety, a late sowing of which will stand through the winter, and furnish a fair spring supply. Other portions of the ground left vacant by lifting the Potatoes should be filled up with Coleworts, Buda Kale, Jerusalem Kale, and other late sorts, for spring use. A bed or beds, according to the demand, should be at once put into a course of preparation for the sowing of prickly Spinach for the winter supply. This crop requires a well-enriched soil, and plenty of room for development, and should never be sown later than grouse-shooting day, the 12th. The last sowing of Carrots to stand through the winter should be got in at once. A warm sheltered border should be selected, and the soil moved deeply and well pulverised, but not manured unless the manure is in the condition of a light decomposed soil, so that it may be thoroughly incorporated with the soil. James' Intermediate and Early Horn are the best sorts for this sowing. A good bed of Tripoli Onions for planting out to stand the winter should be got in at once; a bed also of American Cress and Australian Salad Cress should be sown at once; and the next sowing will be found very useful auxiliaries to the salads through the winter and spring. In light soil on a warm border sow a good breadth of red and white turnip Radish; give them room enough, or if they come up too thickly thin out the crowded parts, and should dry weather prevail they will require watering. If not already sown get in at once the different sorts of Cabbages to stand through the winter. Veitch's Improved Atkins' Matchless, and Carter's Heartwell, the latter smaller, but turns in very early, are two good and reliable sorts. A pinch of red Dutch Cabbage should also be sown either now or at the next sowing. Continue to transplant Lettuces from the later sowings, and see that the necessary sowings to stand the winter are carried out. Beds of Endive from the first sowing should not be neglected, but do not plant extensively of this sowing, as there is always a liability in these early sowings of running to seed. Look well to the continued supplies of water and liquid-manure to Celery, loosen the soil about the plants, but do not be in a hurry to commence earthing-up until about three weeks before its being required for use; this, of course, applies only to the very early ridges, the main crop will require more frequent attention to that important matter. A few rows from the latest sowing in the open border should be planted out for use in the spring. Celeric also should be planted at once in rich soil; this is useful for soups in winter and spring. If Cucumbers and Vegetable Marrows on ridges are to be kept in full bearing they must have liberal supplies of water. Keep Tomatos well thinned out and constantly nailed to the walls. *John Cox, Kallaf.*

THE
Gardeners' Chronicle.

SATURDAY, AUGUST 4, 1877.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, Aug. 7 { Royal Horticultural Society: Fruit and
Floral Committees at 11. General meet-
ing at 3.
FRIDAY, Aug. 10—Cheadle Flower Show (two days).
SATURDAY, Aug. 11—Carmel Horticultural Society's Show.

A THIRD edition of Colonel GREENWOOD'S TREE LIFTER,* published by the executors of the late gentleman, has lately been issued, and it has a special interest now in connection with the views on PLANT NUTRITION advocated by Mr. MURRAY. Colonel GREENWOOD formed one of that small but most valuable class of country gentlemen, blessed with excellent powers of observation and strong common sense, and who know how to apply them to the management of their estates, and the cultivation alike of their cattle and of their plants, whether for horticultural or agricultural purposes.

It must not be forgotten that JOHN EVELYN, and our great physiologist KNIGHT, belonged to this class. With little or no previous study of the subject, KNIGHT set himself to work out many a problem of natural history, and especially of vegetable physiology, with what results we all know. Though he started with little or no knowledge of what his predecessors had done, he soon found the desirability of making himself acquainted with the literature of the subject, sagaciously prompted thereto by Sir HUMPHREY DAVEY.

Reverting to Colonel GREENWOOD, those who remember the original publication of his works and his letters in the *Athenæum* and other journals, will also remember the slashing language which he sometimes used to support his own views, or to attack those of others. We do not now advert to the Colonel's advocacy of transplanting large trees with the tree lifter, so as to secure a large ball of uninjured roots, because this is a matter on which every practical gardener will cordially agree with the Colonel. It is, however, a matter of regret that much more is not done in the way of ornamenting and purifying our road sides and town streets by the transplanting of large trees as urged by our author. The present month and that next following are the best adapted for the process.

We have, however, no intention to discuss this portion of the subject at present. Our present concern is with the "theory of transplanting, or physiology of trees in reference to transplanting," wherein the Colonel gives his views of the way in which trees live, and carry on their vital functions. The perusal of Mr. MURRAY'S paper (see p. 72), it may be stated, furnished the motive for looking once again at what Colonel GREENWOOD had advanced. Having done so we could but be struck with the additional illustration that this book affords that a man may be a very good practitioner and a very wild theorist, and *vice versa*. We find Colonel GREENWOOD, for instance, stating in the most peremptory and dogmatic way:—"That part of the root which is universally believed to imbibe no moisture, the woody part, is the only part which does imbibe moisture; and that part of the root which is universally believed to be the only part which does imbibe moisture, the unripe ends or fibres, is the only part which does not imbibe moisture."! This is pretty well for a beginning. "What faith," we may ask in the Colonel's own words, "is the practical man to place in the theorist who puts him up to such secrets as these?"

* Longmans.

As he goes on, the Colonel discusses the operations of the leaves in a manner that will commend itself to Mr. MURRAY. The carbon, of which plants contain so much, is obtained, says the Colonel, from the soil by the roots, and not from the air by the leaves. Still this does not entirely deprive the leaf of its supposed offices, for, as the Colonel picturesquely says, "the leaf is the turntable which shifts the sap from the up to the down line in summer, as the bud is this turntable in the winter. Summer and winter this traffic is constant; but as it is less in winter, so the plant and staff required to work it is less. Keep your turntables in order or lose your traffic." Unlike Mr. MURRAY, therefore, Colonel GREENWOOD believes in a downward current and a downward growth, and to make the matter plainer it may be well to cite his *ipsissima verba*:—

"That the growth in the girdling, or diameter of trees, is a downward growth, that is, from the descending sap, or at least that the descending sap is necessary for the growth in girth, seems clear from this: If a ring of bark is taken off round a branch of a tree, so as permanently to lay bare the wood, and to intercept the return of the sap through the bark, as long as the branch lives it will continue to increase in girdling above the ring, but not below it; and when such a branch is sawed in two, lengthwise, each additional annual layer may be counted above the ring, but none below it. But if the growth in girdling were deposited from the upward sap, the parts of a branch below the ring would be more favourably situated for it than the parts above the ring; also, if notches are made up a stem, the new growth comes first on the highest, and descends in succession. From these facts it is believed that, after the sap has been elaborated in the leaf, in its descent through the bark it deposits the new growth in girdling. If, however, the sap is elaborated solely in the leaf, and if the growth in girdling is deposited solely from the descending sap in the bark, the growth in girdling of the Plum-stock of a grafted Peach-tree should be Peach; but the stock remains still Plum, its roots Plum, its shoots Plum, and its suckers Plum. On the other hand, if the elaboration were wholly in the root or stem, and the new growth in girdling from the upward sap, the wood and leaves of the Peach would become Plum. But purple Beech and variegated Sycamore grow forever unchanged, though engrafted on common stocks, as a single branch of a plant accidentally variegated will for ever retain its character.

"When Peach scions are grafted or budded on Plum stocks from 4 to 5 feet high, the Plum stocks taper in the usual way, from below upwards; but in the course of years the growth of the Peach appears to overpower the stock, and it will be seen to taper from above downwards. This over-growth says distinctly that it comes from above; but that this over-growth is Plum, not Peach, says as distinctly that it is not solely from above."

The facts just quoted are beyond question. The exceptions, as Mr. MURRAY says, are too few to be of importance from our present point of view. The facts are relied on alike by Colonel GREENWOOD and by Mr. MURRAY, but the use they make of them is rather different. Here, then, we have something like a conflict of opinion, while the facts remain unchanged, *tant pis*, for the theories in this case. Since the original publication of Colonel GREENWOOD'S book much has been discovered and written concerning the source of carbon and the way in which it enters the plant. The mode of growth, too, of the wood, which formerly excited so much diversity of opinion, has been, thanks mainly to M. TRÉCUL, so far explained that the diversities in question are now all but non-existent. The Colonel, or his editor, appears to be quite unaware of this, and a book, originally published some thirty years ago, is, very unfairly to its author, allowed to see the light, not only without any change of text, but without added comment or explanation.

The growth of wood, according to TRÉCUL'S observations, takes place as it were locally. It is not necessarily a downward process, beginning above and travelling downward. Wherever there are cells, vegetable bricks if we may so call them, capable of growing and sub-dividing, there, if conditions be favourable, growth will take place. The scion and the stock are both invested with a

layer or layers of these growing cells—each has its own zone of cells capable of division. Hence it is no wonder that when the stock-cells divide and grow that the product is represented by cells of similar character, and that when the cells of the scion grow they reproduce the scion. Cells have an individuality of their own—they act in common with others on occasion—they feed on the same food, have the same structure, grow in the same way, but for all that they "behave," as the phrase has it, differently. Our own cells afford a parallel illustration. We have blood-cells, nerve-cells, epidermal-cells, gland-cells, and so forth, all originally and fundamentally the same, and nourished with precisely the same food, but each retains its own individuality. The cells of the liver do not take on themselves the office filled by the nerve-cells; neither, when they grow and multiply, do they produce anything else than liver-cells. It is in this distinct individuality of the cells, or of certain groups of cells, that we must, we believe, look for the explanation of very many of the phenomena of plant life. Some of these phenomena are common to the whole plant, others are restricted to particular cells. A supply of food is a requisite of all and every portion of the living plant. What particular use is made of that food, however, depends on various circumstances, of which none is more potent than the individual requirements of particular cells.

— We publish in our present issue the general results of an inquiry throughout the United Kingdom as to the condition and prospects of the POTATO CROP. Speaking generally, we may say, on the evidence obligingly furnished us by our correspondents, that the crop will prove an average one, although the tubers are small, and from ten days to a fortnight later than usual. The Potato disease has made its appearance almost everywhere more or less, and in some cases in an aggravated form.

— We have received several letters on the subject of alleged malpractices at ORCHID SALES at Stevens' Rooms, in addition to those already published. The charges imputed are in some cases of so serious a nature that the attention of the auctioneer and of the vendors must be called to the subject, in order that an explanation may be afforded or a remedy supplied.

— It's an ill-wind, they say, that blows no one any good. The recent confusion of days and dates at South Kensington brought Mr. TURNER to London on Tuesday last, with a couple of boxes of NEW PICOTEES, which he could not exhibit as there was no meeting, and so we had the pleasure of a quiet survey of their lovely contents. Here are our notes respecting these novelties:—Morna (FELLOWES) is a fine medium edged red, of full average size, the white very pure, the marking even and well-defined, and the edge smooth: a very choice flower. Lothair (FELLOWES) is of the same colour, but with a much heavier edge; it is also a larger flower than the last, and has a pure white ground and well-defined marking, but here and there shows a slight roughness on the edge. Princess Mary (FELLOWES) is a full average-sized light purple edge, perhaps rather too full for some tastes, but smooth, pure, and with a clean wire edge of colour. Idalia (FELLOWES) was past its best, but judging from one young undeveloped flower it is a very promising and very pure light rose-edged flower, which the older examples show to be rather over average size. Estelle (FELLOWES) belongs to the full-sized category, and has a light rose edge—so light, indeed, as to be scarcely discernible, and therefore the flower is not an attractive one. Lady Louisa (ABERCROMBIE) is a lovely flower, with heavy rose edge; the petals broad, smooth, and pure, not too numerous, and the markings clear and evenly distributed. Beauty of Cheltenham (ABERCROMBIE) is a light-edged purple, full and large, fairly smooth on the edge, and with a neat and even marking. Miss Frowd (TURNER) is a large, heavy, red-edged sort, very full and high-centred, smooth, with the edge rather irregular, but bright and clear. Whether all these will prove to be acquisitions time will show, but most of them would have taken an

honourable place in any show stand, and appear to be distinct and good—worthy acquisitions to a most charming class of flowers.

— Dr. WITTMACK recently brought to the notice of the Horticultural Society of Berlin fruits of an Indian Crucifer, the seeds of which are now imported into Germany for the large percentage of oil they contain. According to Dr. WITTMACK they belong to *SINAPIS GLAUCA* of ROXBURGH, which HOOKER (*Flora of British India*, i, p. 156) regards as nothing more than one of the many cultivated forms of *Brassica campestris*. The seed is said to yield 35 kilogrammes more oil from 1000 kilogrammes of seed

during the past spring. All are growing freely, and do not appear in the least to suffer from drought.

— The French papers record the death of M. PANCHER, well known as a botanical collector in New Caledonia, and M. L. MAOUT, the author of some excellent educational works on botany, and the collaborateur of M. DECAISNE in the preparation of the text-book translated by the late Mrs. HOOKER under the title *Descriptive and Analytical Botany*.

— Mr. ANDREW MURRAY writes us hoping that the example set by our correspondent "D.," in our last issue, stating his views and experiments on the

vol. xii., p. 154, t. 9). He called it *Echinocystis fabacea*, the specific name being given in allusion to the form and size of the seeds, which, NAUDIN says, one would take at first sight for those of a leguminous plant rather than those of a plant of the family to which it really belongs. The plant, it may be added, proved quite hardy in the climate of Paris; but it is of botanical interest only—that is to say, it possesses no decorative beauty. Dr. GRAY states that on germinating some fresh seeds this spring he was surprised to find that they came up in the manner of Beans. Instead of remaining underground, as from the great thickness of the cotyledons would have been expected, the body of the seed in its shell was raised

FIG. 29.—THE "FULHAM OAK." (SEE P. 139.)

than Rape; and the oilcake from the refuse is, according to analysis, very nutritious, containing 34 per cent. of protein and 10 per cent. of fat.

— Mr. BERNARD DYER, F.C.S., Member of the Society of Public Analysts, of 17, Great Tower Street, London, has been appointed Analytical and Consulting Chemist to the Nottinghamshire Chamber of Agriculture. Mr. DYER holds similar appointments in connection with the Devon County Agricultural Association and other kindred societies.

— Several plants of *FORSYTHIA SUSPENS*A are well established on one of the walls at Kew, growing near the top without communication with the soil. In this position they were self-layered from a tree removed

CIRCULATION OF THE SAP, may be followed by others; and he suggests that instead of his attempting to answer them piecemeal, both they and many other such contributions in other journals should first be taken into consideration by the sub-committee appointed by the Royal Horticultural Society for the consideration of the question.

— There is no phase of plant life more interesting to gardeners than germination. In the *American Journal of Science and Arts* for July, 1877, Dr. ASA GRAY describes the GERMINATION OF *MEGARRHIZA CALIFORNICA*—a cucurbitaceous plant having very large fleshy roots. This same plant was described and figured by NAUDIN, from living cultivated specimens, in 1859 (*Annales des Sciences Naturelles*, série 4,

well out of the soil upon what seemed to be a well developed radicle, like that of a true *Echinocystis*. If the cotyledons had expanded, though remaining fleshy in the manner of *Phaseolus*, the difference between this and *Echinocystis*, with cotyledons truly foliaceous in germination, would be much less than had been supposed. Dr. GRAY waited long to see if this would occur, but in vain, as well as for the appearance of the plumule from between the bases of the fleshy cotyledons. After the lapse of about a fortnight the plumules of those germinating plantlets in a pot appeared separately, and on exposing the whole to view it was seen that the plumules came forth from the base of what appeared to be a radicle 2 or 3 inches long, and below this the thickening of the root, which attains enor-

mous dimensions in old plants, had already commenced. A large amount of the nourishing matter stored up in the cotyledons had been carried down to the root, and used in its growth as well as in that of the plumule. The latter came from a cleft at the very base of the seeming radicle, which otherwise appeared to be solid. But on cutting it across towards the base this was found to be tubular, and later, when more spent, was separable from above downwards into two. This, therefore, says Dr. GRAY, is a case in which long petioles to the cotyledons (of which there is no appearance in the seed), connate into one body, are developed and greatly lengthened in place of the radicle which is thus simulated.

— LILIAM EXIMIUM (longifolium var.) is in great beauty in pots in the Temperate-house at Kew. On a single stem are eleven expanded flowers, and in one of the pots are seventeen flowers. The pots are 24-sized, and in each was placed a single bulb.

— Cutch, or Catechu, and Gambier, or Terra japonica, are two IMPORTANT TANNING SUBSTANCES, the first imported from India, and the second chiefly from Singapore. Cutch is produced by cutting up the wood of *Acacia Catechu* into chips, boiling them, and evaporating the fluid, so as to form an extract, which is made into blocks or lumps and packed in bags or mats for exportation. As it appears in commerce it is a brown, somewhat resinous-looking substance, breaking with a dull fracture and having a strong astringent taste. Its use chiefly is for tanning purposes, and it is also used in small quantities in medicine as an astringent. The quantities of this product imported in different years varies much, but in the year 1874-5 191,891 cwt. were sent from India. Its average value when exported is said to be about 15s. per cwt. About three-fourths of the whole quantity comes from the Burmah ports, and a large proportion from the forests beyond the frontier in Upper Burmah reserves of *Catechu*-producing forest have been formed in Pegu, but outside these reserves the destruction of the trees for the purpose of Cutch manufacture goes on unchecked as before. From the fact that the demand for Cutch is increasing, and from the certainty of a decrease in the supply from beyond the frontier, it is urgently necessary to demarcate extensive tracts of *Catechu*-producing forest in Burmah, so that a permanent supply of the article may be ensured. The tree is stated to grow in all parts of India proper, from the Indus in the Punjab to Ceylon, and Cutch is manufactured in many places in South and Central India, and in the sub-Himalayan forests as far north as the Ganges; but not much of the Cutch produced in India proper is exported. Gambier is a very similar product to Cutch, having much the same appearance and being used likewise for tanning and dyeing. It is produced by boiling the young shoots and leaves of *Uncaria Gambir*, a large climbing shrub, with hard woody hooks or recurved spines. It is cultivated largely in the Straits of Malacca, the product, Gambier, fetching about the same price in the English market as Cutch. Considering the outcry that has been made lately on the scarcity of tanning materials it is satisfactory to know that in India the more general cultivation of the *Acacia Catechu* for the purpose of furnishing increased and continued supplies of Cutch is occupying some attention.

— CALANDRINIA NITIDA is one of the prettiest of all annuals in flower at Kew. The leaves are deeply glaucous, growing in a tuft, and the flowers pink, of large size, growing on stems rather more than a foot in height.

— "ON BLACK MOULDS" is scarcely a title to attract the attention of the general reader, but under such a title we have before us a reprint of a paper read by Dr. M. COOKE before the Quekett Microscopical Club, which contains some good advice addressed to those microscopists and collectors who plod along without any specific object in view, who simply go over the same ground that hundreds have traversed before them, and who never get beyond amusing themselves.

— The SCOTTISH HORTICULTURAL ASSOCIATION bids fair to become a valuable institution. Though only established in March last, four meetings have been held for the discussion of various matters of garden

interest, which have been well attended. More than 150 members have enrolled their names. The subscription is fixed at the moderate rate of 2s. 6d. per annum.

— The death of Dr. PIGEAX, the librarian of the Central Horticultural Society of France, is announced.

— A contribution to SCIENCE from, and printed in, the city of MEXICO, is an occurrence of such rarity that it demands some notice if only to direct to it the attention of scientific men in Europe. But it has another claim on us, as it includes some notes on the flora of a portion of the State of Hidalgo, from Parachuca through Actopan, Ixmiquilpan and Zimapan to Jacala. It is an octavo tract of fifty pages, with a map and coloured figures of *Hiræa Barredæ*, a new species, and of a species of the beautiful genus *Hanya*, perhaps *H. elegans*; and it bears the title of "*Noticia Científica de una parte del Estado de Hidalgo, por MARIANO BARCENA*," Professor of Paleontology and Geology in the national museum. It treats of the physical geography, geology, fauna and flora of a narrow strip of country bordering the road leading through the towns mentioned above. The botanical portion is mainly limited to an account of the characteristic plants on different formations at different altitudes, with a systematic list of the species. Speaking of the forest vegetation of the mountain region of the southern part, the author mentions *Liquidambar styraciflua* as one of the commonest trees, and as attaining truly majestic dimensions. He measured some which were from 100 to 130 feet high; and he adds that the elegant outline of this tree and its beautiful palmately lobed leaves imprint a special character on the woods of these regions. We have repeated what he has to say respecting a tree that he greatly admired, and we will follow it with a translation of a short paragraph relating to a curious bird, called "*El Centzontle*." "*The centzontle*," he says, "is a kind of dictionary or singing catalogue of the birds of the locality in which it lives. It learns all the songs it hears, and amuses itself by repeating them in a more or less regular order, frequently interrupting this sequence with a previously forgotten or recently acquired note." The writer suggests that the specific name of *polyglota* should be given to this bird, which possesses the power of "pronouncing the idioms of all the other birds." The last chapter is devoted to statistics of population, education, natural productions of the country, &c., from which we may make some extracts on some future occasion.

— In the backwoods of America, as stated in the *Indian Agriculturist*, the following method of REMOVING THE STUMPS OF TREES has proved very efficacious. In the autumn a hole 1 inch or 2 inches in diameter, and 18 inches deep, is bored into the stump and filled with 1½ oz. of saltpetre, dissolved in water and the aperture closed. In the following spring half a gill of kerosene oil is put into the same hole and lighted. The stump is said to smoulder away without blazing, and the fire extends to every part of the roots, leaving nothing but ashes.

— On the subject of the CULTIVATION OF CAOUTCHOUC-YIELDING PLANTS IN INDIA a recent report says that it will not be possible to form an estimate of the future yield for many years to come. But considering that the future supply of Caoutchouc to the trade of the world is uncertain, and that the consumption of the article is steadily increasing, it seems right to continue these plantations of *Ficus elastica* on a large scale in one province until further experience may teach us another and more remunerative plan of producing Caoutchouc in India. The experiment hitherto made to raise the two most valuable Caoutchouc-producing species, *Hevea brasiliensis*, a huge tree producing the best Para rubber and *Vahea*, a climbing plant which produces the Madagascar Caoutchouc, tend to show that, in Bengal at least, the long dry and hot season and the low temperature during the winter months are against them. At present, therefore, we must regard the *Ficus elastica* as the most important, if not the only Caoutchouc-yielding tree for India. This, as far as our information goes, is the present state of the question, and Assam being in the midst of the natural range of the tree, is unquestionably the province where its cultivation has the greatest chance of success.

Ficus elastica is also indigenous in Sikkim, but in the present state of forest administration in India, with a small surplus revenue, and a very small staff, which is barely sufficient to do justice to the most pressing works, it is absolutely necessary to concentrate in a few places all operations which require close supervision and a large money outlay at starting, and not to scatter experimental plantations broadcast all over the country. The quantity of caoutchouc from *Ficus elastica* exported from Calcutta in 1874-75, and produced in the forests of Assam and Sikkim, amounted to 15,893 cwt., the value of which is estimated at from £6 to £7 per cwt.

— With reference to the COLORADO POTATO BEETLE, which promises to be "the lion" of the "big Gooseberry" season, we have been favoured by Messrs. HOOPER & Co., of Covent Garden, with the following extract from a letter received from Messrs. B. K. BLISS & SONS, the well-known American Potato exporters:—

"We see by the papers that the Colorado beetle has made its appearance in England. Your people need not be frightened—a few doses of 'Paris green' will fix them. It was feared a month ago that the crop would be destroyed with us, but they were soon disposed of, and the Potato crop never looked better than it now does. From present appearances there will be an abundant crop this season."

Messrs. JAMES GIBBS & Co., of 16, Mark Lane, E.C., and Mr. LOUIS STOLLWERCK, of 145, Cannon Street, E.C., have favoured us with a model of the Colorado beetle in all its (six) stages, manufactured by Messrs. STOLLWERCK BROS., of Cologne, by order of the German Government, after the specimen and larvæ found near Cologne at Mulheim-on-Rhine. The retail price of these models is 2s. each, and, with a view to make the British agriculturists thoroughly acquainted with this insect, so that it may be easily recognised should it reach our shores, Messrs. JAMES GIBBS & Co. have purchased 10,000 of these models, which they are distributing, free of all cost, to the principal landowners and leading agriculturists throughout the United Kingdom. Seeing how much is being done to make the appearance of the insect generally known, there should be little excuse for mistaking a friend for a foe, as was done at Hereford the other day.

— On the occasion of the recent exhibition of the Kirkcudbright Floral and Horticultural Society, Mr. JAMES SERVICE, nurseryman, Maxwelltown, was presented with a handsome marble timepiece, along with a silver teapot for Mrs. SERVICE, in acknowledgment of the hearty interest which he had always taken in the exhibitions of the Society, and of his exertions to promote their success. Lord SELKIRK, who made the presentation, remarked that he understood Mr. SERVICE had been one of the most zealous promoters of the exhibitions, and he thought it alike honourable to himself and creditable to his brother horticulturists that his exertions should be thus publicly acknowledged.

— The third part of the third volume of HANSTEIN'S *Botanische Abhandlungen* is wholly devoted to a paper embodying the results of the joint researches of the late Dr. A. BRAUN and Dr. HANSTEIN, ON THE REPUTED PARTHENOGENESIS OF *CŒLEBOGYNE ILICIFOLIA*. To Mr. JOHN SMITH, so many years Curator of Kew Gardens, belongs the credit and honour of having first observed and recorded (*Transactions of the Linnean Society*, xviii., p. 509, t. 36) the singular phenomenon exhibited by this Australian plant, of producing perfect seeds without any apparent action of pollen. Since the publication of this unexpected occurrence several other observers have paid some attention to the subject, and several other supposed instances of parthenogenesis have been recorded. In spite of all this corroboration there were many—and doubtless there are still—who would not accept the fact because it was contrary to long-cherished theories. Parthenogenesis has been observed, it is believed, in *Xanthoxylon Bungei*, by DURIEU; in *X. alatum*, by Hanbury; *Dodonæa hexandra*, by FR. VON MUELLER; *Aberia caltra*, by ANDERSON; *Carica Papaya*, by BERTHELOT; *Ficus*, by GASPARRINI; *Excoecaria marginata* and *Torreya nucifera*, C. BOUCHÉ; *Cucurbitaceæ*, NAUDIN; *Cycas*, A. BRAUN; and the subject is now exhaustively treated in the place quoted above.

THE POTATO CROPS OF 1877.

SCOTLAND.

Aberdeen.—Potatos here are fully a fortnight behind the average seasons. The old Ashleaf I am now using are particularly fine, and with me all the sorts seem very luxuriant. In this neighbourhood I only hear of one instance of disease—a patch a few yards square, and 2 miles north. During the past week the weather has been all that could have been desired, from which I am in hopes the disease will be staved off till the tubers are more matured. *R. Farquhar, Fyvie Castle Gardens, July 28.*

—Potatos now present a fine appearance, although fully a fortnight behind time. I am afraid of disease attacking them soon, the weather being so dull and damp and the haulm so succulent. *G. Donaldson, Keith Hall, Inverurie.*

Argyll.—The only drawback to the Potato crop in this district is its unusual lateness, for otherwise the plants look vigorous and promise well for a crop, both on the low ground and high-lying land; and if anything could show more clearly than another that the vital energy of the Potato is not exhausted, it is the circumstance of the Potato retaining, as it does at present, the healthy spread of foliage in such cold, sunless, wet months as June and July have been, measuring as they did 7 and 8 inches rainfall respectively. Of course everything depends on the weather in the future, not only for the Potato, but for every other crop. At present the weather could not be worse than it is. *John Cais, Inverary.*

Banff.—The Potatos are healthy and vigorous, both in gardens and fields everywhere in this district, but later than usual by ten days or a fortnight. *J. Webster, Gordon Castle, July 26.*

Berwick.—The Potato crops are not looking so well as usual, and are at least fourteen days later than usual. *Peter Loney, Marchmont House, Dunse, July 26.*

Caitness.—The Potato crop is quite free from disease, but, owing to the cold spring, they are three weeks later than usual. If we get favourable weather there is every prospect of a heavy crop. *J. Sutherland, Langwell, Berriehale, Wick, July 30.*

Clackmannan.—Early Potatos are very good, and other crops looking well but late. *Thomas Ormiston, Alloa Park Gardens.*

Dumarton.—Potatos look well in this district, and no disease has appeared up to this date. *James Mitchell, Camis Estean, Helensburgh.*

East Lothian.—Potatos are looking well, but ten or fifteen days later than ever I have seen them during thirty-five years. On heavy soils in East Lothian they are a very indifferent crop in the fields. *Alex Shearer, Yester Garden, Haddington, July 31.*

Fife.—The appearance of the Potato crops is generally good, and a good average yield is expected. The fields generally have a full healthy growth. *Robert Foulis, Fordeil, Inverkeithing.*

Forfar.—The lateness of the season has been much against Potatos here, they are therefore small and poor in quality as yet. The haulms are, however, remarkably strong and healthy, and, with a little more time and heat, good results may be expected. No signs of disease here, nor in the neighbourhood, so far as I can ascertain. *George Johnstone, Glamis Garden, July 31.*

Lanark.—The Potato crops have still a very healthy and luxuriant appearance both in gardens and fields, and no trace of disease is as yet observable on the tubers. *Andrew Turnbull, Bothwell Castle, July 27.*

Mid-Lothian.—Early Potatos have been fully three weeks later than usual in being fit for use, but they are now of good size and excellent quality, with no taint of disease, and ten days of fine weather would put them past danger. Late Potatos are growing luxuriantly, and promise a fine crop, and although the weather has, till within the last few days, been favourable to the appearance and spread of the disease, still there is no symptoms of it, and if the present dry breezy weather continues they may get over the critical stage without any serious injury. Some strong healthy kinds are blooming profusely. Among a few sorts "earl" has appeared to a slight extent, but is not spreading, and is not nearly so bad as it has been in some recent years. Early Rose and some other American sorts seem to suffer most from it. Hay is a heavy crop, but suffered badly from heavy rains while being made. Grain crops look

very promising, but the harvest will be ten days later than usual, even with fine weather till then. Turnips are looking first-rate. *M. Dunn, Dalbeth.*

Moray.—Early Potatos are not a good crop this season, owing to the summer being so cold and wet. Late kinds promise well. *Donald Cunningham, Dornaway Castle Gardens, July 28.*

Nairn.—I can scarcely say how they will turn out yet. They seem to be prolific but very late, and if this damp sunless weather lasts much longer I am afraid our old enemy the disease will spoil them. The field Potatos about here look quite healthy, but smaller in the stalk than usual. Dry and sunny weather is much wanted for all crops, whether in the field or garden. *J. Mailland, Cawdor Castle, July 30.*

Perth.—The Potato crop has not looked worse here for many years. Amongst early kinds nearly a half are diseased. *John Browning, The Gardens, Dupplin Castle.*

Renfrew.—Potatos are everywhere round here in want of good weather. In gardens they look well and turning out a fair crop, with no sign of disease. In fields, however, they are not up to their usual appearance, being in many cases stunted-looking, and the braird did not start as regular as the farmers would have wished. They are much later this year, and with dry weather they, no doubt, would improve to a great extent. *John Methven, Blythswood.*

Ross-shire.—The crops in this district are very vigorous; the haulm is getting very strong, and there is no disease. *James Laing, New Tarbat, Parkhill, July 28.*

Sutherland.—No symptoms of disease have as yet appeared in this neighbourhood; the haulm seems healthy and strong. Early kidneys are, however, scarcely so strong as usual, and I have never observed such a large proportion of the sets come up with the crop quite sound as is the case this season. *D. Melville, Dunrobin Castle Gardens, July 30.*

Wigton.—Potatos look well; no disease is to be seen in this district, and no report of its existence has reached me; but, like every other crop, they are from two to three weeks later than usual. *Archibald Fowler, Castle Kennedy, July 26.*

ENGLAND—NORTHERN COUNTIES.

Northumberland.—Our Potatos are very good both in quantity and quality. No sign of any disease yet. Our main sorts are Rivers' Royal Ashleaf and Myatt's Prolific. I have grown them three years, and they have never failed in being a good crop. *William Turner, Caphsaton, Newcastle-on-Tyne, July 31.*

—A good and plentiful crop, with no appearance of disease as yet. *A. Ingram, Alnwick Castle Gardens.*

Cumberland.—The Potatos in this district look well, and in most cases have a large quantity of top, owing to the continual dark droopy weather. The first early Potatos are lifting small, and are more soapy when cooked than they have been for a good many years. I have not seen any appearance of disease on the top yet, or heard of any in this neighbourhood. *John Taylor, Isl Grange, July 31.*

Westmoreland.—The Potato crops here look remarkably healthy, but very late. No appearance of disease as yet. *William Shand, Louther, Penrith.*

—A good crop, and very healthy. The season in Westmoreland has been very unfavourable to crops in general—much rain, little sun, and the temperature very changeable. *C. Sandford, Underly Hall, Kirkby Lonsdale, July 31.*

Durham.—Potatos look remarkably well, and I hear of no disease at present. *Robert Draper, Seaham, July 26.*

Yorkshire.—Kidney Potatos are good, and free from disease. Late sorts look healthy. *James Fowler, Harewood House, Leeds, Au. 1.*

—The crops are not so vigorous as usual, and the disease has appeared here and there in the district. The variety called Snowflake was early affected in the foliage in several gardens about here. In some of the plants the stems are quite decayed, and there is no crop at the roots. The rainfall during June and July, up to this date (July 26), has been 4.77 inches. There has been very little thunder. *J. Simpson, Wortley Hall Gardens, Sheffield.*

—Potatos all looking remarkably well. I am taking them up daily, and can find no signs of disease as yet. *William Lewin, Aske Gardens, Richmond.*

—The Potato crops are in general very

promising at the present time, both in the garden and the fields, but the early kinds were nearly three weeks later in coming into use than they have been for some years, owing, no doubt, to the long continuance we had of cold dull sunless weather; up to the present time they are free from disease. Dry bright sunny weather would now be beneficial to them. *M. Saul, Stourton, July 31.*

—Potatos, as with most things here, are very late; they are however looking very promising. I have not yet seen anything of the disease, nor heard anything of it in this neighbourhood. *John Young, Wentworth, Rotherham.*

—Early Potatos have been a good crop, but quite a fortnight later than usual. The disease has shown itself in several places, especially in wet low-lying situations. Later crops look fairly well, but not so much so, accordingly, as the early crops. There are large quantities of Potatos grown within a few miles of this—Scotch Regent is the variety most grown; the seed is purchased in Scotland, but several growers tell me they get the best crops from seed grown one year in England. *H. J. Clayton, Grimston.*

—Healthy, and promising well for a good crop. I have heard of but few complaints yet of the disease. *Robert C. Kingston, Brantingham Thorpe, Brongh.*

Lancashire.—Potatos being late, I can give no opinion as to how they are likely to be in regard to disease. Vegetation in this part is at least three weeks later than I have ever known before. *Henry Lindsey, Huntroyde Gardens.*

—Early Potatos are not so good as usual. There are a good many blanks in the rows, and the tubers are small. Later crops are looking very well. No sign of disease yet. *W. B. Upjohn, Worsley Hall Gardens, Manchester, July 26.*

—Potatos look well generally, but the kidney sorts run rather smaller than last year, and a few diseased ones have been found. As yet no round ones have been found. Everything about here is later than usual. *F. H., Knowsley, July 27.*

—Potatos, like other crops, are unusually late; early crops have been unsatisfactory; numerous, but uneven in size. Late crops look promising, and up to the present time are free from disease. *A. Jamieson, Haigh Hall, Wigan, July 31.*

—Potato crops here are abundant, the quality and yield excellent, and no appearance of disease. *W. Hinds, Otterspool, July 30.*

MIDLAND COUNTIES.

Cheshire.—The Potato crop this season may be considered good so far. Early sorts have improved much this last week; second earlies are scarcely commenced on yet, owing to the lateness of the season, but to all appearance there will be a good yield. Late ones look well. Very little disease at present. *Alfred J. Grant, Withington Hall, Chelford, July 30.*

—The crop may be said to be about an average. There is little or no sign of disease, but it is early yet in the season for it to make much appearance. *R. Macbellar, Abney Hall, Cheddle.*

—Up to the present time the Potato crops have been very good in quantity and quality, but about a week later than usual in coming in for use. The plants and tubers are healthy and free from disease, but I have just seen some Myatt's Prolific and Dalmahos, growing in a rather damp and shaded place, which showed the usual symptoms of disease on the leaves and stalks, and on examining them a few diseased tubers of the Dalmahos were found, but none of the Myatt's were diseased. I have also heard of the disease having made its appearance in some of the gardens in the neighbourhood, but it is as yet rather too soon to judge as to what extent it is likely to prevail. The kinds I find to succeed best are Mona's Pride, Veitch's Improved Ashleaf Kidney, Dickson's Improved ditto, Early Coldstream, Yorkshire Hero, and Bryanston Kidney. *Wm. Whitaker, Crewe Hall, July 30.*

—The crops in this district are good, though late. I have not seen any diseased ones in the gardens here; I have only heard of its appearance in one or two places. *W. Muir, Oulton Park, Tarporley.*

—Potatos look remarkably well, especially the later kinds. Very little disease has shown itself yet. *T. Selwood, Eaton Hall Gardens, Chester, July 28.*

Derby.—The Potatos around this district look very healthy, and free from disease. Our early varieties

turned out well, but the tubers were smaller than in former years. The late crops are promising an excellent yield with well formed and large tubers. *J. W. Bayne, Kingston Hall Gardens, July 26.*

— Up to the present time the Potato crop throughout this district looks most promising, and with fine weather will be unusually good. We find Veitch's Ashleaf the earliest, Rivers' Royal the heaviest cropper, and Hammersmith Kidney of the best quality. Fox's Seedling Round is an enormous cropper. All the American kinds are deficient in flavour, no better croppers, and quite as subject to disease. *H. Goodacre, Elvaston, Aug. 2.*

— The crops in this neighbourhood look well, but yesterday a neighbour of mine showed me some of Myatt's Prolific very much destroyed with the dry rot. *William Brown, The Gardens, Braby Park, Burton-on-Trent.*

Notes.—The Potatoes are looking better than ever I remember them at this time. No signs of disease as yet. What we have been getting of Royal Ashleaf has been very fine-flavoured. *A. Henderson, Thoresby Park, July 30.*

— Up to the present we have seen no signs of disease, but they are late. *Henry Gadd, Wollaton Hall Gardens, July 30.*

— The Potato crops in this district are at present looking healthy, and the early sorts now being lifted are productive and excellent in quality. Some symptoms of the fungus have appeared here on Snowflake, but owing to the low temperature in the last two weeks in July the disease has been arrested. A great rise in the temperature, however, occurred on the 29th, and if a rainy or showery period sets in, I am afraid the Potato crops will be doomed again. Last year the disease first appeared on some of the American varieties of the early ripening section, and on a standard sort of Mr. Fenn's raising, named Rector of Woodstock. This was in the end of July, but the weather in August was very warm and dry, and the disease made no progress till the heavy rains set in in September, when the late varieties of Potatoes were attacked, and great losses were sustained by large growers in the warp lands in this district. *William Tilly, Welbeck.*

Salop.—Potatoes are an excellent crop, but disease has made its appearance in the neighbourhood on wet land. *William Pratt, Hawkestone Gardens, July 30.*

— The Potato crops are good though late. I found a few diseased tubers on July 20; the fatal black spot is showing itself amongst the foliage and stems of the late Potatoes, though it does not appear to be spreading very fast. *George Pearson, Attingham Gardens, Shrewsbury, July 31.*

— Our early sorts are somewhat small this year, which I attribute to the dry and cold weather in May, but I am glad to say they are sound in every respect at present. I fear the rains will cause them to renew their growth till late this autumn. Late Potatoes look remarkably well at present, and I anticipate a good crop, but it is too soon to speak definitely as to produce or quality. *A. S. Kemp, Haughton, Shifnal August 1.*

Stafford.—The Potatoes, both early and late, are looking well in this district, but are quite a fortnight later than usual. I have heard of a few cases of the disease, but have not witnessed any myself. *O. Thomas, Drayton Manor.*

— Potato crops look exceedingly well generally; early varieties are a fine crop, especially Lee's Hammersmith Kidney, which is one of the best early sorts that has come under my notice. Late sorts are looking very promising, and apparently free from disease. *E. Simpson, Wootlesley, Wolverhampton.*

— Potatoes are excellent, free from disease and looking remarkably well. Late crops have very much improved since rain fell. Carrots and Onions are very much attacked with grub. The second Peas are poor, and want sunshine to bring them on. First earlies did well, and late Peas will be good. *Thos. II. Rabone, Alton Towers.*

Leicester.—The Potato crop was exceedingly promising, but the disease has made its appearance here, and in most of the gardens in this neighbourhood. *M. Henderson, Cole Orton Gardens, July 30.*

— Early Potatoes have given a fair produce. Later kinds under favouring showers have thrown up a large amount of haulm, which at present is very green and vigorous. No sign of disease has appeared. *W. Ingram, Belvoir Castle Gardens, July 29.*

Warwick.—This is not by any means a Potato neighbourhood seeing that its culture is mostly con-

finied to gardens and allotment gardens, but generally speaking about here the Potato crop may be pronounced a fair and prosperous one, rescued perhaps from partial failure by the timely rains which fell during the first weeks of July. I have heard of but one echo of disease so far, and nothing at all of the Colorado beetle. This beetle, according to the *Illustrated London News* of July 14, appears to enjoy no larger immunity from the preying of other smaller beetles than the flea immortalised in rhyme:—

"Little fleas have smaller fleas
To worry and to bite 'em;
Smaller fleas have lesser fleas—
And so ad infinitum."

With the assistance of the said *Uropoda americana*, which makes it a special business to plague the Colorado beetle to death, let us hope that when the enemy does appear amongst us that we shall be enabled to show him a front which knows nothing but total extermination, bag and baggage. *W. Miller, Combe Abbey.*

— The tops are looking healthy, and as yet I have heard of only two or three small instances of the murrain in this district. This is also the case here with only such as Lee's Hammersmith Kidney and Alpha—sufficient, however, to create alarm as to the state of ensuing crops. *William Gardner, Ealington Park.*

Beds.—Potatoes in this neighbourhood look strong, and promise heavy crops. Disease is breaking out in many places, both in the haulm and tubers. *A. McKay, Woburn Abbey, July 28.*

— The crops are looking well at present, but the disease has made its appearance in places. A dry time will now be very beneficial. *G. Ford, West Park, Ampthill.*

Bucks.—We have already lifted early plantings of such sterling sorts as Veitch's and Rivers' Ashleaf Kidney, also another named Princess Louise, "Gilbert," and found these kinds to be wholly free from disease, and the crop and quality to be all that can be desired. The appearance of later kinds are also still promising, but there are evident traces of the presence of disease already in the haulm of some kinds, especially in the American varieties. In the surrounding district the disease is unfortunately very rife, and the tubers already much affected, Early Rose being amongst the worst in this way. We shall proceed to lift all early kinds which were planted at the ordinary time without delay, in order to avoid contagion. *Geo. T. Miles, Wycombe Abbey.*

Herts.—Potatoes look well everywhere in this neighbourhood up to this time. *Anthony Parsons, Daesbury, Welwyn, July 26.*

Oxford.—Within the last few days some of the American sorts, particularly Early Rose and Snowflake, show unmistakable symptoms of the disease. The leaves have got much spotted, and even at a distance small disagreeably. *John Greenshields, Sarsden House, Chipping Norton.*

— Early Potatoes were fully ten days later than usual, and on the whole an inferior crop. We had them all cut down to the ground with spring frosts. Later kinds grown in the fields look very promising, and there is no sign of disease at present. *Isaac Watson, Nuneham Park.*

— A large portion of the early Potato crop suffered much by the severe frosts of the first week in May. Such as escaped are an excellent crop of fine quality—Veitch's and Myatt's Ashleaf well sustaining their standard reputation. Rector of Woodstock, Early Market, and other of Mr. Fenn's seedlings, are also a grand crop. Their skins are quite clear, and up to this time we have not found a diseased one. This may be the result of the good dressing of gas-lime with which the ground was dressed previous to planting, as I hear of disease being found in several places in the immediate neighbourhood—indeed one's nasal organ corroborates this. Late kinds all look remarkably well in fields and cottagers' allotments alike. *W. Crump, Blenheim Palace Gardens, July 30.*

Northampton.—Potato crops are looking very well, and there is every appearance of a very heavy yield. Myatt's and Victorias are the principal sorts grown here. Last year I lifted my Victorias the third week in August, and laid them in small lots, and out of a large quantity I had not a dozen bad Potatoes. Others in this neighbourhood that left them in the ground until the autumn lost nearly all. *John Smith, Althorp Gardens, July 28.*

Rutland.—Our crops are very good indeed, with no trace of disease at present, but I am afraid, from the heavy fall of rain which we have had in this neighbourhood during the latter part of last month (July), which amounted to nearly 4 inches, that we shall hear of the disease before long. *F. Clarke, Barleythorpe.*

— Good. *Mark Hull, Ayston, Uppingham.*

EASTERN COUNTIES.

Lincoln.—Potato crops are very promising in this neighbourhood, some slight cases of disease have been seen, but not of any importance as yet. Early Potatoes have turned out well, although they were cut down to the ground by frost in the beginning of May. Early Alpha, Early Sovereign, and Vermont Extra Early very heavy crops; Veitch's Improved Ashtop, a first-class early Potato; Early Bird, a new Potato, very early, with me the earliest of all Potatoes and a fair cropper. *D. Lumsden, The Gardens, Bloxholm Hall.*

— All kinds of Potatoes here, both in the garden and field, are good, and show no signs of disease at present. *Isaac Dell, Stoke Rochford, July 31.*

— The first and second early Potatoes yield abundantly, and are free from disease. The late crops about here are very thin in the rows, and the haulm very wiry. *Wm. Hurst, Sowerby Park, Gainsborough, July 30.*

Norfolk.—The crops looked remarkably well until the end of this month, but after heavy rain and damp, cold nights, succeeded by hot sunshine, the old cry is out again. *J. Wighton, Cossey Park Gardens, Norwich, July 28.*

— Early Potatoes are being taken up with an over average crop of good-sized tubers, clean and free from murrain. The Early Rose has been in a great many places arrested in its growth through the haulms being attacked by the disease as in the last two seasons, but the tubers are clean and of a good size; all late varieties are looking extremely well, promising a great crop. They are clear at the present from the effects of the Peronospora, excepting in very damp localities. *Wm. Bishop, Bylaugh Park, July 27.*

Suffolk.—The early sorts of Potato are a fair crop, and free from disease; but I hear that on some of the heavy lands disease is showing itself. The most promising kinds are Snowflake, Vermont Beauty, Peckless, and Early Rose. All the sets came up, have grown well, and, from appearance, I expect a good crop. The showery weather has kept them growing, and as there is no probability of a check for want of moisture we are not likely to have a second start from the tubers, which has been so prevalent for some years past. *Thomas Blair, Shrubland Park, Aug. 1.*

— Owing to the wet state of the ground, and the cold, unpropitious spring, early Potatoes have not been so good as usual, either in quantity or quality, as they were greatly checked in their swelling, and had not sufficient leaf and haulm to develop fine tubers. Late ones, however, have not looked so well for years, as the warm weather and genial rains came at the nick of time to send them rapidly into growth, and since then a fresh heavy fall has taken place that will be sufficient to carry them through, as the tubers are now getting to a good size. Unfortunately disease has again made its appearance, but if the present weather continues it is to be hoped that crops will not suffer to any great extent. Should the spread of this malady be arrested an abundant supply of first-class quality now appears a certainty. *J. Sheppard, Woolverstone Park, Aug. 1.*

— Ours were all dressed with Salus; they came up very slowly, and with more blanks than usual. Most of them were cut off level with the ground in May, afterwards the east winds and the long drought held them in check, but for the last six weeks their growth has been extraordinary. There is an immense crop of tubers, and a full average of tops at present, all sound, in these gardens. But the disease is abroad in the neighbourhood in rather a new phase—it has made little or no progress on the stems but completely destroyed the tubers in many cases. More of the plants have also died off than usual, though this seems quite different from the disease. *D. T. Fish.*

— I have not up to the present seen any appearance of disease among our Potato crops; all the early sorts yield well, are good in quality, but rather small, which I attribute to their being cut down by the frost and the long drought which we experienced here after the crops started into growth again. *J. Mill, The Gardens, Rendlesham Hall, July 30.*

Essex.—The Potatos in this neighbourhood are a fair crop, the early ones rather small, being cut down with the frosts. Late ones very promising. The disease has made its appearance during the last few days on the second earlies. *J. Bryan, Audley End Gardens, Saffron Walden.*

— Early Ashleafs good, and harvested; other second earlies (Snowflakes, Paragon, &c.) now developing a good crop. Rust has made its appearance upon many stocks, but we have only seen one where the real murrain has actually appeared in the tubers. *William Early, Valentines, July 30.*

— Very good. *W. Bones, Havering Park, Romford.*

SOUTHERN COUNTIES.

Berks.—The early crop of Potatos was a good one, and the later ones are very promising at the present time. *Thomas Jones, Royal Gardens, Frogmore, July 28.*

— The crops about here are very good, especially early sorts, which are very clean and full-sized. Later kinds are not so good. Complaints reach us already respecting the disease, which seems to be making considerable progress in some soils. *A. Gall, Aldermaston Court, Reading.*

— The disease showed itself nearly a month ago on the haulm, but did not spread much till about the 28th of this month, and now most of the American, and also the English varieties with smooth leaves, have got it; those sorts with rough or curled leaves are still clear of it. Very few of the tubers are yet affected. The mid-season and late varieties are much later this year than usual. *Charles Ross, Walford Park, Newbury, July 31.*

Middlesex.—The earlier planted sorts suffered somewhat by the frost. A great many blanks have been caused also by the "curl," or that form of disease on which the resting-spores of the *Peronospora* were found so abundantly two years ago. Of the true disease, the first spots were observed on July 23 on a plant of Regents. These having been gathered for investigation, no further trace has been observed up to this date. Two fully diseased tubers were, however, found, where no trace of it on the leaves could be found. The disease is spreading fast in the neighbouring market-gardens. Generally, the crop promises to be good. *A. F. Barron, July 30.*

— At present the Potatos are looking remarkably well; no disease has, so far, shown itself. Early kinds are very good, dry, and of excellent flavour; Veitch's Royal Ashleaf especially so. *T. P., Stanmore.*

— Potatos in many places came up badly—in some cases, with the early sorts, not more than one-half or two-thirds, and then very weak. On examining these I found that the seed was rotten, leaving the sprouts without any support. These, though they have grown, have few and very small tubers at them. I have seen no signs of disease. The crop is abundant and good in quality, but later than usual. *T. Baines, Southgate, July 31.*

— The Potato disease has made great progress during the last few days. *John Woodbridge, Syon Gardens, July 31.*

Surrey.—At present the Potato crop presents a better appearance than for two or three years past. *Wm. Denning, Coombe Lane, Kingston-on-Thames.*

— The crop here is very good; though the early ones were cut down by frost they broke again. We are now lifting some of the best tubers of Covent Garden Prolific, Early Fortysfold, Rivers' Royal Ashleaf, Victoria Kidney; Bresee's King of the Earlies and Fox's Seedling we have had for years. Late kinds are looking well here at present, but I hear rumours in the locality that disease has made its appearance in some damp places, and, as we are near the water, I fear we shall not escape. *William Kemp, Albury Park, Guildford, July 30.*

— Are looking well, and promise a good crop. Early kinds show signs of disease in places. *J. Child, Garbrand Hall, Ewell, July 30.*

— Potatos are an excellent crop round here, and very good, though quite a fortnight later than usual. The Potato disease has begun in several places in the haulm, but I have not yet observed any of the tubers touched. *J. Burnett, The Deepdene, Dorking, July 30.*

Kent.—All through this district these are looking very strong and healthy; the early sorts are coming out very clear from disease, and of good size and quality. *John Cox, Redleaf, Penshurst, July 30.*

— Potatos are looking well. Tubers are already a great size. Early Rose lovely and quite ripe. *Henry Cannell, Swanley, August 1.*

— Our Potato crops look very promising and quite free from disease as yet. *C. Hylcock, Barham Court, Maidstone, July 31.*

— The Potato crop will be an average one, but the size of the tubers is not expected to be very large. There is no disease at present, but I hear of it in adjoining districts. *Lewis A. Killick, Mount Pleasant, Lang'ey, Maidstone.*

— The crops look well at present. *R. Gray, Chevening Gardens, Sevenoaks.*

Sussex.—Early Potatos are very fine and free from disease, but I am sorry to say that it is spreading very much amongst late sorts. *John Wilson, Castle Gardens, Arundel, August 1.*

— At present there is every prospect of a fine crop. *J. Rust, Eridge Castle, July 26.*

Hants.—Ashleaf Kidneys were a fortnight later than usual this year, but there is an average crop free from disease. The principal early kind grown in this part is the American Early Rose, and everybody seems to have a good crop of them, but the disease has made a general attack on the haulm of that variety. The tubers are not affected much at present. I am sorry to say traces of disease are also visible in the haulm of the second early kinds. The late varieties are looking remarkably well, and at present show no signs of disease. *James Taverner, Woolmer Lodge, Liphook.*

— Early Potatos were very good, but rather small. The disease has just begun its work of destruction in many places, and the haulm of second earlies is fast going. Late sorts look well as yet, but it is too early in the season to make any report on them. *George Harnett, Cadant, Southampton, July 30.*

Wilts.—The Potato crop is light, and the disease in its worst form appeared before the later kinds had made much progress. According to present appearances, I anticipate a Potato famine here before winter. *Wm. Taylor, Longlat Gardens, Warminster, July 27.*

— The Potato crops are very good indeed, but I am sorry to say they indicate disease in the haulm. *W. Phillips, Boswood Gardens, July 26.*

Dorset.—An excellent crop. Not much affected with *Peronospora*. *W. F. Radcliffe, Oxford Fitzpaine.*

— The early sorts are a very good crop, and in most cases will be housed before the disease has done much damage. The late ones have suffered for want of rain; and, owing to their being so backward, and the disease setting in so early, the prospect must be a very poor one. *W. G. Pragnall, Castle Gardens, Sherborne.*

— The Potato crop, until within the last fortnight, looked very healthy and promising; but a great change has occurred during the past week, the disease having made serious progress, many pieces being stricken down before the tubers are scarcely formed, so that there is every prospect in this neighbourhood of a great scarcity of the poor man's staple commodity. *Henry Munro, Clevedons.*

WESTERN COUNTIES.

Hereford.—Potatos are in very good condition. Some little disease has shown in the haulm, but we have not found it communicated much to the tubers. I have planted all my crop with Salus. Myatt's Prolific still holds its own; Yorkshire Hero is one of the best; Coldstream, though small, a good early round. *William Ward, Stoke Edith Park.*

— Early planted Potatos having been cut off during spring frosts, the tubers are small, but good. Late planted kinds, including Lapstone Kidney, which I grow extensively, are promising. Disease on heavy soils and in low damp situations is now spreading throughout this district. *W. Coleman, Eastnor, July 28.*

Worcester.—Crops generally good, but slight traces of disease appearing in some of the early kinds. Should the fine weather of the last few days continue, early crops may possibly be taken up before serious damage is done. The success of the later sorts will much depend upon a continuance of dry weather, in which case we may hope for favourable results. *W. Cox, Madresfield Court, July 30.*

— The early sorts are looking well, and are an

abundant crop. The late sorts are looking promising. The tops of the American Rose are showing signs of the disease. *John Wyle, Kyre Park, Tebury.*

— So far the Potatos are free from disease, and the early kinds are producing heavy crops; but I hear much about the blight being on the move in neighbouring localities, and I fear it will be serious should the wet weather continue. So far I have not perceived a single diseased tuber. *Geo. Westland, Witley Court, July 30.*

— Over an average crop, and very good, but the disease is very bad, more especially among the American sorts. *Geo. Holman, Gr. to H. Bramwell, Esp., Crown East Court.*

Gloucester.—In this district the Potatos appear to be very satisfactory at present. Although disease has made its appearance in several places, the early sorts have turned out very well, but later than usual. Should the disease spare them, some heavy crops may be expected. *W. J. Simpson, Kingscote Park, Wootton-under-Edge.*

— The Potato crop is so far very satisfactory. The tubers are not quite so large as usual, but the yield is good; and at present I have not seen the slightest trace of Potato murrain. *Thomas Shingles, The Gardens, Tortworth Court, July 31.*

Somerset.—In this district the crops are very good, and so far tolerably free from disease. I am glad to find that a great many in this neighbourhood are beginning to adopt the plan of pulling the haulms as soon as the disease makes its appearance. I say glad, because I feel confident if done immediately it makes its appearance it will be the means of saving the crop. I have adopted this method here during the last five years, and have not lost a bushel-basketful by the murrain during that period, whilst some of my neighbours lost in some seasons the greater part of their crops. *Thomas Foot, Clevedon Court.*

— The early kinds, although rather small, have been sound and good. Up to July 22 the main crops looked very promising, since then, however, the disease has set in, and is now very rife. *John Austen, Ashton Court, Bristol.*

Devon.—Early Potatos were in many cases cut back by late frost, and even where they escaped being nipped they made little progress in the early part of summer owing to the excessive cold and wet we experienced, and are, in consequence, a light crop, and very backward. I regret to report the appearance of the disease about three weeks ago in the Snowflake and other American sorts. It spread slowly at first, and confined itself to these sorts for a time, but for the last few days we have had a heavy fog, and it seems spreading rapidly now in the other sorts. I dread the ultimate result. *A. Ayson, Oxtou Gardens, Kenton.*

— Potatos, both early and late, look very bad, and if the weather continues so hot and humid the disease will be very bad indeed. In many places the haulm is quite black with disease now. *Alfred George, Bilton Gardens, July 30.*

Cornwall.—The disease has been very visible for five or six weeks past, and the late rains have developed it to the entire destruction of the stems. I fear the tubers of the late kinds will be small, inferior in quality, and badly decayed. *J. Tyerman, Tregony, July 31.*

— The early crops suffered from the east wind, the yield being in some instances a great loss. The late Potatos looked well a week or so ago, but the disease has made its appearance, and with the rain we are having it is hastening the decay of the haulm. *H. Mills, Enys, Penrhyn, July 26.*

WALES.

Anglesea.—A good many Potatos are diseased in this neighbourhood. *R. Webster, Glyn Garth.*

Brecon.—Potatos are late this season. Early ones were promising till about a fortnight ago, since then the disease has attacked them badly. Late ones looking well. *F. J. Ireland, Glanusk Park, Crickhowell, July 31.*

Carmarvon.—The Potato crops are in good order all round the county. *Allan Calder, Faynol Park, Bangor, July 30.*

Denbigh.—Potatos have been very slow of growth, but look well, although the haulm is not so strong as usual; but no disease has as yet appeared out of sixteen sorts. The most abundant scourges of the garden have been slugs and mildew. *P. Middleton, The Gardens, Wynnstay and Llangedwyn, July 26.*

Merioneth.—Potatos this season are very good, and

have been much improved by the late rain. Rivers' Royal Ashleaf and Lapstone are splendid crops. Early Rose will be discarded after this season. It does not suit this locality at all. All late crops look well. No sign of disease at present. *James Bennett, Rhug Gardens, Corwen, July 28.*

Radnor.—The Potato crop is good both in quantity and quality, and no disease is to be seen. *John Weatherston, Boultibrook, Presteigne.*

IRELAND.

Antrim.—Potatoes are very inferior, and are about three weeks later this season. *D. Taylor, Glenarn Castle, July 30.*

Armagh.—A good field of Potatoes is the exception, and not the rule, in this county. Farmers for the most part were late in getting in the crop. Many of the fields appear thin, showing a considerable number of blanks. However, the late rain has improved the appearance of the crop a good deal, but if disease sets in early I fear the produce will be light. Tubers small and imperfectly matured. *W. Allan, Brownlow House Gardens, Lurgan.*

Cavan.—Everywhere around this neighbourhood the late Potato crop looks well. There is no sign of disease, and heat and dry weather are all that is wanted to bring the tubers to maturity. A most promising crop. Early Potatoes turned out deficient in size and quality, owing to the cold, wet weather, which has continued since the time they were planted. *W. F., July 27.*

Cork.—Early Potatoes are very much under the average. The late crop is promising a full yield, with the exception of some failures in seed. The disease is setting in very much. *J. Fraser, Bessborough, Aug. 1.*

Dougal.—The Potatoes this year seem to be the worst crop we have had for many years past. They are three weeks later in this district than usual, and the disease has set in very badly, owing to the continual wet weather. *Armstrong Hanon, Drumboe Castle, July 30.*

Down.—The crop is quite three weeks later this season than usual, and by appearance will be but a light one in this district. Early Dons are not fit for using here yet. *James Taylor, Mount Stewart, July 28.*

Dublin.—From the vigorous appearance of the Potato fields all through the country, and the fine samples of sound tubers coming into the market, we seem to be in a fair way for an abundant yield of the national root. Varieties of the Ashleaf section grown in old garden soil are frequently tainted with disease by the middle of July, but there are no appearances of it up to the present (July 30), but every indication of robust health. *G. Smith, Vice-Regal Lodge, Dublin, July 30.*

Fermanagh.—The Potato crops are looking very well, the tops are strong and healthy, but they are very late. Any that have been dry are small and soft, no doubt in consequence of the damp weather. *John McDonald, Florence Court, July 31.*

Kerry.—Early crops are bad, but late ones have at present a good appearance. No indication of disease yet. *A. Gilmour, Killarney House Gardens, July 27.*

Kildare.—The Potato crops, owing to the cold wet spring are very backward, although at present looking well and free from disease. Some of our neighbours met with great loss this season from the imported seed refusing to grow. One farmer in particular planted over 10 acres, which was a complete failure, and had to be ploughed up. What could be the cause? Would the salt water destroy the power of germination? *W. A. Emery, Kilkea Castle, Kildare.*

Kilkenny.—All early planted Potatoes are looking well, and there is every prospect of a good crop. In garden varieties the blight has made its appearance, but not nearly so much as at this time last year. *G. Dodd, Woodstock Park, July 30.*

King's Co.—Early Potatoes, notwithstanding the ill-treatment they had to encounter, being on one occasion cut down to the ground by frost, are turning out remarkably well, prolific, large, and good. Veitch's Improved Early Ashleaf, and Rivers' Royal Ashleaf, are all that could be desired. American Early Rose has got to an immense size, but are watery, and we are beginning to find a good many diseased ones amongst them. Late ones have looked very promising hitherto, but the stems are now showing signs of disease. *T. F. Harl, Birr Castle Gardens, Personstown, July 30.*

Leath.—We hear from the farmers of this district a general complaint—the continuous wet having

injured the crop, disease has set in both in field and garden. *Frank Fowler, Ravensdale Park, Newry, July 31.*

Meath.—Where very late in starting into growth and where they were above ground, the frost cut them down again. We had a few hot days in June, then they grew away for a time, then came more rain and very cold with it to, frosts several nights, and everything was at a standstill, ground cold and wet, nothing green but weeds. For the last few days it has been much warmer, Potatoes are improving, but the haulm in some places is quite black; I have found several bad tubers, and the good ones are very soft. The best here are the Flounders, Early Rose and Climax. I expect a very bad season. *John Clews, Headfort.*

Queen's Co.—The crop is a very good one so far. I have only heard of one case of disease, and that of a slight nature. *J. Ennis, Emo Park, Portarlington, July 30.*

Sligo.—The Potato crops are a good average in this district, but I am sorry to say the disease is making its appearance in some places. *J. White, Hazelwood Gardens, Sligo, July 27.*

Westmeath.—The Potatoes are looking well, but not coming to maturity as early as last year. The corn crops of all sorts are above the average. Meadows in general are very fine—far superior to anything experienced during the last ten years. *John Igo, Moydrum, Athlone, July 31.*

Wexford.—I was obliged to lift the early and second early crops of Potatoes a fortnight ago, owing to the disease setting in so much earlier this season than usual: it made its appearance about June 22. Until the last week the Potato crop was in general good, more especially the late crop, but now the disease has set in in its worst form. I fear the produce will be small, on account of the very wet weather preventing the farmers from planting them until May. *P. Braund, Courtown House, Gorey.*

Wicklow.—Notwithstanding the late cold spring which caused many of the sets to rot, Potatoes at the present time are looking well, and quite free from disease. Early kidneys were somewhat small, owing to the dry cold winds prevalent here when they should have been making rapid growth. Now the earth is well watered with the late rains, Potatoes are making great growth, and promise to be a good crop. *Chas. Penford, Powerscourt, July 27.*

CHANNEL ISLANDS.

Guernsey.—Very good so far. *T. C. Bréhaut, Richmond House, July 30.*

Home Correspondence.

The Colorado Beetle.—The sublime Doryphora is fast degenerating into a *ridiculus mus*. Newspaper correspondents vie with each other in seeking to obtain for their respective localities the honour of first introducing the beetle to our Potato pastures, even their blind zeal converting the useful little ladybird into this terrible Colorado bogey. Dublin, Glasgow, and now Hereford, have wired the entomological intelligence all over the kingdom, only to raise eventually the jeers and laughter of the public. The cry of "wolf, wolf," will be raised too often, and when the real enemy does come people will be ashamed to make his *locale* known. Chambers of Agriculture are affected with the general scare, and madly call upon the ducal head of the House of Lennox to "stamp it out"—the agriculturist panacea for all ills—even before there is anything to destroy. What with cattle-plagues and Colorado beetles the Lord President must find the cares of office even heavier to bear than his quadruple coronet. Those who shout in alarm "Stamp it out!" should remember Mrs. Glass' celebrated advice "first catch your hare," and, difficult as that operation oftentimes is, they may expect catching the beetle to be considerably more so. If during the present session of Parliament some honourable member had brought in a measure to render the beetle subject to heavy customs' dues, we should have found his incursions effectually barred

at every port in the kingdom by a noble army of Customs' officers. *D.*

The Crops in my District.—Slugs are a good crop, both late and early. Snails are plentiful, and promise to be more so if not interfered with, which they probably will be. Worms looked well at one time, but were terribly nipped by the early birds, from which they have not recovered, and are not likely to do. Grubs, beetles, and woodlice are numerous and thriving. Green-fly is a very abundant crop, and cover the branches everywhere. Some people wish they didn't, but you can't have everything. If you have green-fly you can't have Roses; if you go for Roses you can't have green-fly—experience shows it. Weeds of all sorts are abundant, the late rains having brought them on like magic. It is a curious thing about weeds that they require neither top-dressing nor manure, bedding out, nor banking up: leave them alone, don't mess them about, and the crop is perfection. Try Celery that way, and the result is entirely different. Why? Damsons are a good crop—we have one. We have not settled whether to pickle or preserve it: it will depend on the market price. Cherries none, but there are two in the next garden. A crop of that kind ought to be looked after, so the sparrows have undertaken the job. Pears were plentiful, so were the early frosts and east winds. The winds remained, the Pears didn't. As before remarked, you can't have everything. Apples are plentiful. When a market gardener thinks of his landlord he looks at his Apples. We have three; at least, we had three yesterday. I am not sure how many there are to-day; everything is so uncertain, you cannot even depend on Apples. Observation: A man who looks to pay his rent with three Apples and one Damson cannot expect much change, unless it is a change of quarters. Work is scarce; few people have more than two hands, and they not fully employed. *T. W. B.* [Our correspondent hails from the neighbourhood of Chiswick. His report is an unusual one, but so is the season. *EDS*]

Black Currant Bud Disease.—Is there any known effectual remedy for this disease, caused by the Acarid as described in your articles in the *Gardeners' Chronicle* of 1869, p. 841, also 1876, p. 703? It is committing great havoc, and in some districts has entirely destroyed all prospects of fruit, and baffles all the usual remedies of compounds, washes, &c. A remedy if known would be a great boon more particularly to those small cottagers who, hitherto, have depended on this valuable fruit as a means of eking out their incomes, but who now find that source cut off. Of course I cannot state to what extent this disease prevails over the country, but I heard of it first in the Glasgow district, extending to Killearn, thence to Balfour and Fintry, and now I hear of it being seen in Stirling this year for the first time; and, unless a remedy be found, there is no saying how far it may spread. I have asked three of the leading gardeners in the Fintry district, as being a district in which it is very bad, but without success. Two could give no cure but to destroy the bushes, but then they did not grow the fruit to any extent. The third, whose proprietor utilises his surplus by sending it to market, told me he had been fighting the disease for about seven years, and had tried everything he could think of, transplanting, subsoiling, &c., thinking the fault lay in the soil, for, although he gets your paper, he did not know the cause until I called his attention to your article last year; and although he has been trying various remedies since, he has not hit upon anything effectual. *T. G. D.*

Summer Flowering Plants.—Amongst flowering plants to be admired at this season, for an evergreen climber nothing can surpass *Escallonia macrantha*. I send you some blooms from a plant, 6 feet by 4 feet, that is covered. *Spiraea arifolia* is also covered with its fine white flowers; *Deutzia crenata flore-pleno*, pink; *Magnolia glauca* in fine bloom. Amongst Roses—Chamois, very little known, fawn colour; *Souvenir de la Malmaison*, Baroness Rothschild, Général Jacqueminot, Gloire de Dijon, and *Maréchal Niel* will always command a place. *Clematis Jackmanni*, *C. Star of India*, *C. rubro-violeacea*, and *Passiflora cerulea* deserve a place in every garden. *J. M., Bogshot, July 25.*

Destructive Insects in New Zealand.—I have lately received a letter from a friend in New Zealand, asking my advice how to deal with the larva of *Blennocampa*; he tells me that at Picton in the province of Marlborough it has become a most serious pest, so injuring Apple, Pear, Plum, and Walnut trees, as to entirely destroy the crop of fruit. Now of course, although I have seen a few of these fellows on Pear trees before now, and got rid of them by dusting them with lime, I feel incompetent to give advice as to dealing with them on such a large scale. Is there not a change in the larva as it becomes well fed? Is not the slimy skin

moulted, and a smooth skin assumed? If so I fancy in that state they might be beaten off the trees, though of course they would already have done great harm; or would it do to dig round all the trees for the pupæ, or encircle the trees with troughs of water, &c., so as to catch the larva when descending for entering the earth? If this were done all over a district their numbers would be kept down. But if you can recommend any plan which has been found to succeed, I shall be thankful if you will insert it in the answers to correspondents in your next issue. *H.* [We are afraid this is a hopeless case. In this country no better plan has been found than that noticed by our correspondent himself, viz., dusting the leaves on which the larva are with slaked lime, but how to deal with whole orchards of standard trees is still a desideratum. On one or two incidental points which our correspondent queries, we can answer. The species is not a *Blennocampa*, it belongs to Hartig's third section of *Tenthredo*, which he calls *Eriocampa*. At its last stage the larva ceases to be slimy, becomes orange, and descends into the earth, where it makes a kind of cave or cocoon in which to undergo the metamorphosis. *A. M.*]

The Peaches at Scone Palace.—An eminent gardener and his successor having said that the pot Peach and Nectarine trees in the cast-iron structure here were all dead, I wish to say that their foliage never looked better than at present, and that there is a collective number of 727 fruit among ninety-two pots, twelve young ones bought in this spring not being reckoned, or about eight on the average. The poor fellows could not have known what they were talking about when they jumped at such conclusions and floated such a tale as that. This house still maintains its reputation, having sent the first Figs and second six Peaches to the International last year, as it did the first Figs and three pot Peach trees in fruit years previous at the same place on the meeting of the British Association. Lest to cover the first mistake another should be made by saying the plants must be dead and replaced by fruiting ones—a by no means impossible feat, and the less so as no fault would have been found had such been done—I shall be glad to show the stock to any of your district correspondents, and leave them to say whether such stock appears to be of recent acquirement. But for my information coming from high quarters I should have taken no notice of it. The pot plants are not so vigorous as when you saw them ten years ago, age beginning to tell on them. *John Halliday, Scone Palace, July 31.* [From a statement of the number of fruit on each tree, taking them *seriatim* as they stand in the house, we learn that five trees have over twenty fruits, the highest number being twenty-three; twenty-five have from ten to nineteen; twenty-six from five to nine; twenty-eight from one to five; and eight are fruitless. *EDS.*]

Roses: the "Amende honorable."—I am sorry that I left out these noble Roses from my late list—1, *Sœur des Anges*, most beautiful, daughter of the Duchess of Orleans, still one of the best light roses; 2, *Lady Suffield*, quite lovely. I named *Star of Waltham*, it is *A1*, and good in all respects. I have since had of Saint George (W. Paul), named in my lists (page 19), some extra blooms. I may say in passing that Mr. George Paul does not do justice to Lord Clyde (page 118): "Really these old Roses are not worth further fighting about." I cannot agree to this. The Duke of Edinburgh is nearly scarlet, and Lord Clyde is one of the best in the line of crimson. I have had the plants for years, they are as good as ever and better, and the blooms when "D." of Deal was here, and at this time, were and are most noble. I should not like to give up the authorship of Lord Clyde, but I agree with the Editors that "enough has been said." My opinion is, that in the line of crimson *Lefebvre*, *Alfred Colomb*, *Marie Rady*, *Lord Clyde*, *Prince de Poitia*, *Maurice Bernardin*, *Duchesse de Caylus*, *Dr. Andry*, *Annie Wood*, *Maréchal Vaillant*, *Madame Victor Verdier*, *Sénateur Vaisse*, *Lord Macaulay*, *Baronne Adolphe Rothschild*, *Lady Suffield*, and *George Prince* are the best. The last is not much known. Mr. Turner gave it to me years ago with eleven others. I have only one plant of it, and have overlooked it. It is a grand Rose, and a survivor and free bloomer. It is in *Van Houtte's Catalogue* thus:—"George Prince (396), beautiful dazzling red, very large, full, and some 4 inches across." It is a globular Rose. I must caution the nurserymen, and advise them not to turn away Roses at the suggestion of every conceited fellow who thinks himself and is supposed to be a judge of Roses! *Madame Knorr* is one of the sweetest scented and the finest in bud for buttonholes. Don't turn her out! *W. F. Radclyffe.*

Reclamation of Land.—"Agricola's" land may be in much the same state as land called saltmarsh on the banks of a tidal stream, which is often left bare by alterations in the course of the river, and then enclosed by a sea-wall, and soon becomes first-class

land, as, for instance, the marshes on the banks of the Medway. There the farmer first gets his land dry, and then sows it with a succulent grass, called there "Lamb's-tongue," but about Hampshire it is, I believe, called "Pen-grass." Nothing thrives on salt soils so well as this plant, and sheep are very fond of it. It is fed off with sheep, and gradually brought into first-class grass cultivation. I have walked in the Medway marshes on grass as high as my knees, and as thick as a Turkey carpet within ten years after being covered with the tide. *J. H. Veitnor, August 1.*

Orchid Sales.—I see some letters respecting the naming of imported Orchids in your last two or three numbers. I buy a good many of these, and I do not expect that they should all be true to the name given them. If I wish for accuracy in this particular I give a larger price than I expect to buy plants for at Mr. Stevens' auction room, to a nurseryman, whom I expect to be answerable for the correctness of the names given to the plants which he sells. I do not think that Mr. Stevens could possibly be responsible for the correctness of the names of the vast quantities of imported Orchids which go through his hands, but I am glad to see in the last catalogue which I have received from him a (?) to some doubtful lots, and I hope that Mr. Stevens will continue this whenever, either from his own knowledge of these plants or otherwise, he has any reason to doubt the accuracy of the names. *C. W. Strickland.*

Lilium cordifolium.—I feel much obliged to Herr Max Leichtlin for his notice of the flowering of the above Lily. I believe I was privileged to flower *Lilium cordifolium*, *L. sinicum*, and *L. Wallichianum* the first time in Europe. All these bulbs were sent home by Mr. Fortune, and certainly the cordifoliums of that day seem to my memory as mighty giants compared to the cordifoliums of to-day. Whether a quarter of a century has dimmed my memory or not I cannot say, but in my mind's eye the leaves were something like 18 inches in diameter. It would be interesting to learn if the progeny of these two (there were only two bulbs brought home) still exist. If I remember rightly they were sold to Messrs. Thibaut & Keteleer, Paris. *Lilium Wallichianum* was lost soon after flowering; *Lilium sinicum* did well for some few years, but was afterwards lost, and partially forgotten until recently, when the love for these beautiful flowers re-introduced them. *Charles Noble, Bagshot.*

Red Rose for a South-Eastern Aspect.—Either of these four crimson Roses will suit your correspondent to climb against a white house with a south-eastern aspect:—1, *Madame Clémence Joigneux*; 2, *Glory of Waltham*; 3, *Vicomtesse de Vézins*; 4, *Madame Louise Carique*. The last is not large, but it is most effervescent, blooms late, and never gives deformed flowers. It is not large, but it is extra hardy. Some years ago Mr. Sturt, now Lord Alington, and Viscount Walden, now Marquis of Tweeddale, came here to spend the day; they were much struck with this Rose as an ornamental Rose, planted, like a leech-bite (three together, 8 feet high), between Conifers and Deodars. They said, "that is the prettiest thing we have seen." Mr. W. Paul, of whom I had my plants some years ago, can supply it. It is, in my judgment, though not a show Rose, the best red H.F. climber. The others are noble Roses; 2 is a free bloomer and sweet; 3 is a noble Rose, of great size, hardy, free bloomer, and sweetly scented. I have forgotten the scent of 2, but have a sweet remembrance of it. It is not here now. If size and scent were not required, the best red Rose for a white wall is the red Bengal. It blooms till Christmas. *W. F. Radclyffe, Okeford-Fitzpaine.*

Irish Yew seems to be an instance of that not very rare deformity in which a plant (especially a coniferous one), in place of forming any side shoots, produces nothing but leading shoots. All the plants that I have raised from Irish Yew berries are exactly like the common Yew. *C. W. Strickland.*

Reports of Societies.

Royal Horticultural of Aberdeen: July 19.—The annual summer exhibition of this Society was held on the Links, and, considering the very backward nature of the season, the show was a most successful one. The specimens exhibited in the amateur classes were especially commendable, and showed a marked improvement on former years.

The exhibits were arranged in two main divisions. The first was confined principally to professional gardeners, but it was open to amateurs, also to the working classes on certain conditions. The plants in pots in this division were divided into twenty-five classes, and, to non-professional visitors at least, were one of the main attractions in the exhibition. For

nine stove or greenhouse plants the cup was carried off by Mr. Dalgarno, gr. to J. M. Paton, Esq., Links House, Montrose. Among Mr. Paton's collection was a *Dipladenia Brearleyana* worthy of notice, the colour being exceptionally rich and beautiful. A fine specimen of *Allamanda Hendersoni* was also very well flowered. *Crotons Disraeli* and *mysticum* were likewise included, and the collection was made up of a number of young plants, which have been apparently well managed. In the second class the 1st prize was awarded to Mr. Roberts, gr. at Granton Lodge. Amongst noticeable features in this lot was a pretty specimen of *Anthurium crystallinum*; an *Alocasia metallica*, bulky enough, but deficient in colour. There was also a well-grown plant of *Clerodendron Balfourianum*, but past its best. A fine specimen of *New Zealand Flax*, shown by Mr. Leiper, gr., Craigmyle, attracted some attention, and was included in the lot which came in for a 3d place. For the best stove or greenhouse plants, Mr. D. Kennedy, gr., Strichen House, carried off the prize. The Tree Ferns were a poor show. For the best collection of Ferns from the stove or greenhouse, Mr. Roberts, Granton Lodge, carried off the prize. Most worthy of notice in this group was an exceptionally meritorious *Adiantum gracillimum*. The feathery structure of this plant is very marked, and its general appearance is most handsome. The exotic Ferns generally, while not at all in advance of the standard of former years, were nothing behind it. The British Ferns deserve special notice. They improve yearly, and are becoming quite a feature in connection with this show. This is very gratifying, and indicates the prevalence of a spirit among exhibitors which ought to receive all encouragement. The number shown included some very pretty specimens sent both by practical gardeners and amateurs. The *Pelargoniums* on the tables presented no remarkable feature. Some of them had evidently been in better condition a week ago, but seemed now to be shorn of a good deal of their beauty. In the class of six *Pelargoniums*, variegated leaved, the half-dozen which carried the prize were without exception the finest that have ever been shown in Aberdeen. They were, indeed, something remarkable, and out-distanced by a long way all their competitors. With respect to *Fuchsias*, there has generally been a very good show in former years, but those on the tables on this occasion seemed in advance of any we have yet seen placed. While a general improvement was noticeable in the plants shown, the numbers were not quite so large as before. Orchids, which usually lend a peculiar grace to most shows, were rather conspicuous by their absence. There were a few on the tables, but they call for no special comment. Of *Caladiums* and *Marantas* it was gratifying to observe a good show, the former especially being remarkably well coloured. *Lycopods* were a poor display, as compared with last year, but some of the little specimens on the tables were almost perfect. The 1st prize was carried off by Mr. Grigor, gr. to Mr. Stronach, at Sunnybank. Among the plants for table decorations were some very tasteful displays, the best ten coming from Links House, Montrose. In this lot was a *Cocos Weddelliana*, which was quite a gem in its way. In the 2d prize lot there were some very well-grown plants from Strichen, but the quality possessed no special merit. Among the cut flowers the effects of the bad season were very noticeable. In the competition for twenty-four dissimilar Rose blooms, open to nurserymen only, exhibits were of very fair quality, but were not up to the usual mark. For eighteen Rose blooms, the cup presented by Messrs. Cocker & Sons, Sunnypark, was carried off by Mr. Donaldson, gr. to the Earl of Kintore, with a remarkably good collection considering the very adverse circumstances which have had to be contended with in rearing them. The cut *Pelargoniums* were of an average quality. Stocks were good, Mr. Roberts, Granton Lodge, being 1st. The bouquets were in advance of those shown last year. The great fault of those intended for buttonholes seemed to be that they were too large. Among the hand and table bouquets were some very carefully and tastefully arranged. Those composed wholly of wild flowers were exceptionally good. The 1st prize for the latter class was taken by Mr. W. Jaffrey, Banchoy Gardens.

The backward season has, of course, told to a very considerable extent on the fruit. Strawberries were numerous, but quality was wanting. For best flavour Mr. Peckham, gr., Garthdee House, was 1st, and for size Mr. A. Westland. In the classes open to market gardeners only Mr. W. Davidson was successful in carrying off the two 1st prizes. Vegetables, for the season, were a wonderful show. For the best collection in baskets there were four entries by gentlemen's gardeners, and three by market gardeners. In the former Mr. Ogg, gr., Fintray House, was 1st, with a capital collection, the excellence of quality being noticeable in all the descriptions the basket contained. The Celery was remarkably mature, and the Rhubarb was splendid. Mr. J. Kinnaid, Outseats, Rubislaw, was 1st among the market gardeners with an excellent basket also. In fact, there was not a bad specimen

in it, and the judges were of opinion that a more uniform collection in point of superiority was never exhibited at any show in this part of the country. In the collections of round and kidney Potatoes Mr. W. Smith, gr. at Rothie-Norman, was 1st with the best specimens in the tent. In fact, the judges were quite astonished at the superior quality of this exhibit. Mr. Ogg, Fintray House, was 2d. The Rhubarb was nothing remarkable in point of quality. The size of some of it was very noticeable, but the fibre, if one might use the expression, was remarkably coarse. Cucumbers were a good show, the 1st prize going to Keithhall House. There was a large quantity of Cabbages on the tables, but none of them were of more than average merit.

The number of exhibits in the second and third divisions was quite equal to that of former years—a fact which is very gratifying, and the quality on the whole was good. To stimulate a taste for the cultivation of flowers among the working-classes is a most laudable object, and it is to be hoped the Society will always continue to encourage it as far as possible. There was a large collection of plants in pots shown in these divisions. Among them were some very pretty Pelargoniums, and in this and other classes Mr. Mitchell, Leadside, carried off a number of prizes. He was both 1st and 2d for Petunias with excellent specimens, surpassing anything of the same kind shown by professionals. The exhibits of Clematis were very good. In the centre of the table was a towering *Lilium auratum*, shown by Mr. Mitchell in capital flower, which attracted considerable notice. The Rose blooms were of a very high order, and were quite equal in point of merit to those exhibited by the more practical competitors. Mr. Sadler, Banchoy-Ternan, was 1st for a choice little group of six; and Mr. R. Watson, Stoneywood, for a group of four. There were few Pinks shown, but those on the table were creditable considering the season. Pansies were very much in advance of those placed last year. Stocks were a good show, and so were the herbaceous plants generally. The bouquets compared very favourably with those in the professional division, and showed no less taste and care in their selection and arrangement.

In the amateur department the vegetables call for no special comment. For the best basket of varieties, Mr. Forrest, Nigg, was 1st, and Mr. R. Watson, Stoneywood, 2d. The kidney Potatoes shown by Mr. W. Milne, gr., Burnside, and the round by Mr. Watson, were especially fine specimens of their classes. The Shallots in the working-class section were the finest some of the judges had ever seen, and called forth their highest commendation.

There were a number of most attractive plants exhibited, but not for competition, by Messrs. J. Cocker & Sons, Sunnypark, and Mr. R. Connon, East Seaton, Old Aberdeen. For two most meritorious Gloxinias they received a First-class Certificate. Mr. Connon's collection embraced a specimen of the *Cocos Weddelliana*, *Dracenas*, a remarkably showy *Begonia Vesuvius*, with very fine foliage; a pretty little *Achimenes Williamsii*, and a variety of other plants. Some of the specimens in both the Messrs. Cocker's and Mr. Connon's collections were rich in flower, and their presence enhanced considerably the general appearance of the show.

Royal Horticultural: July 24.—A meeting of the FRUIT COMMITTEE was held at Chiswick to examine subjects grown for trial there this season. Henry Webb, Esq., in the chair.

The Gooseberries, of which there is an extensive collection growing, were first examined, a small basket of each variety (200 in number) having been gathered for comparison and classification. The committee selected the following varieties as especially worthy of cultivation, viz.:—Reds: Red Champagne, Warrington, Monarch, and Starling. Green: Roseberry, Overall, Green Globe, Pitmaston Green Gage, Cheshire Lady, Shiner, and Gretna Green. Whites: Whitesmith, Orleans, Keepsake, Safety, and Topgallant. Yellow: Sulphur, Rumbullion, Aston Hepburn, and Yellow Globe.

RED CURRANTS.—These were examined with great care as to their nomenclature, so much confusion still existing amongst them in that respect. Of the most approved varieties noted, the earliest and the largest is the Red Cherry, which has the following synonyms:—viz., Bertin No. 9, Grosse Rouge de Boulogne, Fertile d'Angleterre, La Hâtive, La Fertile, Fertile de Bertin, Hâtive de Bertin, Chenonceau, Belle de St. Gilles, Fertile, Fertile de Pallau, and La Versaillaise.

The Red Dutch, which is the variety most generally cultivated in gardens, rejoices in the following synonyms:—Knight's Large Red, Knight's Sweet Red, Goliath, Fielder's Red, Palmer's Late Red, Pitmaston Red, Pitmaston Prolific, Large Sweet Red, Bertin No. 1, Dancer's Selected, and Jackson's Mammoth.

The Red Grape, a long-bunched sort, of a pale red. Synonyms:—Rouge Transparent, Queen Victoria, Fertile de Pallau.

Houghton Castle, the best constituted variety. Synonyms:—Houghton Seedling, Orangefield. A fuller report of these will appear in the Society's Journal.

TURNIPS.—An examination of the Turnips, of which about 150 varieties are this season being grown, was then made, and the earliest was the Green Strap-leaf (Carter & Co.) Tomatoes were also examined, a very large collection of which is being cultivated in pots, the only one showing signs of ripening being Early Gem, sent by Messrs. Veitch & Sons. Of these a later examination will be made.

A meeting of the FLORAL COMMITTEE was held at Chiswick on July 25—George F. Wilson, Esq., in the chair—for the examination of the various collections of plants growing in the gardens for trial this season.

ZONAL PELARGONIUMS.—Of these a large selection of the most approved newer varieties which were grown in pots last season have been bedded-out along with some of the best older sorts for comparison. First-class Certificates were awarded to Mr. J. R. Pearson for Atlas, a large-trussed crimson-scarlet Nosegay; Rev. A. Atkinson, crimson-scarlet. To Messrs. James Cocker & Sons for John Fraser, light magenta. To Mr. J. George for Mrs. J. George, rosy cerise; and Beauty of Surrey, crimson-scarlet, very free, and excellent habit. Of the older varieties conspicuous for their excellence were noted Vesuvius, Princess of Wales, Vesta, Cleopatra, Violet Hill Nosegay, and Claude de la Meurthe, &c. Of the newer varieties which have been sent out this season, and grown in pots under glass, First-class Certificates were awarded to Mr. J. R. Pearson for Rebecca, a very beautiful magenta-scarlet Nosegay; Louisa, a sort of shaded magenta-pink mottled with rose; Blanche Gordon, light pink. To Mr. J. George for Lord Mayo, bright scarlet. Specially noticeable also were Miss Wakefield, Lizzie Brooks, and Lord Giffard.

BEDDING VIOLAS.—A large collection of those reported on last year are again under cultivation, the most noticeable amongst them being Crown Jewel (Grieve), Blue Beard, Blue Bell, Queen of Lilacs, Lilacina, Rubra Lilacina, Princess Teck, and Pilgrimage. Of new varieties First-class Certificates were awarded to Mr. R. Dean for Vestal, a pure white variety of a fine free habit; to Messrs. Dickson & Co. for Holyrood, a very rich dark blue variety of good habit; to Mr. Fromow for Golden Prince, a clear yellow variety with distinct white eye.

BEGONIAS.—A fair selection of these have been grown in pots, chiefly of the tuberous-rooted class, the most striking being Acme and Kalista (Veitch), Frebeli, &c. A First-class Certificate was awarded to a seedling from *rosæflora* raised at Chiswick, and named by the Committee Mrs. Barron. It is of very robust growth, forming a large plant; flowers large, roundish, and produced freely, of a pale rose pink; a very distinct sort. Moonlight, a hybrid raised by Col. Clarke and certificated last year, is exceedingly attractive. This, which is something of the habit of *weltoniensis* and producing long racemes of pure white flowers, will become a very popular decorative plant.

FUCHSIAS.—Of these a selected collection has been grown, occupying one house. A First-class Certificate was awarded to Messrs. Laing & Co. for Lord Beaconsfield, a hybrid from the old fulgens, and possessing a good deal of its character. As a free-blooming decorative plant it will prove very valuable. Very conspicuous amongst others is Champion of the World, a very large dark double sort—almost a monster.

VERBENAS.—Only a few varieties of these are on trial. For habit Purple King still stands pre-eminent. Blue Bell (Smith) is very effective. A First-class Certificate was awarded to Mr. John Fraser for Carl Sieglig, an intensely dark blue variety of good habit.

HARDY ANNUALS.—Complete collections of Iberises, Clarkias, Godetias, Vicarias, Dianthus, Stocks, Balsams, &c., are on trial this season, and when in full flower are exceedingly showy. Of Iberis First-class Certificates were awarded to Messrs. Vilmorin et Cie. for two splendid novelties, viz., *I. coronata hybrida nana rosea*, a variety of fine dwarf growth with large rosy salmon flowers, not unlike *gibraltaria*, and exceedingly beautiful; *I. coronata hybrida nana alba*, a variety of the same character, with pure white flowers. Amongst the Godetias, Lady Albemarle, which was certificated last year, is by far the finest. Of *Viscarias* none exceed in beauty the true *V. cardinalis*.

Mr. Charles Turner, Royal Nurseries, Slough, sent cut blooms of his seedling *Roses Penelope Mayo* and Harrison Weir. This latter variety is of a rich dark crimson colour, and is a promising variety. The committee highly recommended it, at the same time requesting that it be again brought before them, being unable to give a final decision from seeing only one bloom.

Kendal and District Horticultural: July 26. —The Kendal flower show takes high rank among the exhibitions held in the North of England; it is

well officered and managed, and the committee work together with a will to make their floral festival a success. For a few years past two shows were held annually, but the committee have returned to the old and wise practice of having but one, and making that as attractive as possible. The present show was regarded as the most successful ever held in Kendal.

In the matter of stove and greenhouse plants there was a fine display, for handsome prizes were open to all comers for a collection of twelve plants, six at least to be in flower. The best group came from T. M. Shuttleworth, Esq., Preston (Mr. H. Thornber, gr.). Too much praise cannot be given to this splendid lot of plants, for they were in fine condition. The foliage plants comprised *Cocos Weddelliana*, *Croton undulatus*, *Dasyliiron gracilis*, *Cordylone indivisa*, with a wonderful development of leaf; *Phormium Colensoi* (?) variegata and *Cycas revoluta*. The flowering plants were *Erica Parmentieri*, and also its rose-coloured variety; *Stactis profusa*, *Ixora Colei*, *Anthurium Scherzerianum*, and *Bougainvillea glabra*. The plants were all of the freshest character, and as nearly perfect in development as plants could be expected to be at this season of the year. 2d, the Earl of Bective, M.P., Underley Hall (Mr. C. Sandford, gr.), who had *Allamanda Hendersoni*, *Erica Antiohia superba*, *Ixora Williamsii*, *Dipladenia boliviensis*, *Bougainvillea glabra*, *Anthurium Scherzerianum*, *Croton Weismanni*, *Caryota urens*, *Lantana borbonica*, *Dicksonia antarctica*, *Croton pictus*, and one other. This was a good well-balanced group. 3d, H. W. Schneider, Esq., Bellsfield (Mr. C. Chaplin, gr.), who had *Croton variegatus*, *C. angustifolius*, *Gleichenia flabellata* and *Davallia Mooreana* in remarkably fine condition; but was weak in flowering plants, or he would have assuredly taken 2d place. As it was, Mr. Sandford only just gained 2d position. An extra prize was awarded to the Preston Nursery Company, who staged good examples of *Cycas revoluta*, *Cocos Weddelliana*, *Eurya latifolia variegata*, *Allamanda Wardleiana*, *Dicksonia antarctica*, and *Stephanotis floribunda*. There was also a class for four stove and greenhouse plants in flower, and here Mr. Sandford was 1st, Mr. C. Chaplin, 2d, and the Preston Nursery Company 3d. In the class for six exotic Ferns the Preston Nursery Company was 1st, Mr. Chaplin was 2d, and Mr. Sandford 3d. The best specimen was a fine example of *Croton Disraeli*, from Mr. Thornber; and Mr. Sandford and the Preston Nursery Company were equal 2d—the former with a well-grown and flowered *Ixora Williamsii*, the latter with *Aralia elegantissima*.

In the lake district generally hardy Ferns are a great feature, but at Kendal they are grown with marked success, and some very choice and singularly well-developed forms, both British and North American, could be found in the collections. The 1st prize twelve, staged by Mr. T. Wilkinson, Kendal, one of the Secretaries of the Society, were remarkably well done, and comprised *Trichomanes radicans*, three unique varieties of *Scolopendrium vulgare*, a fine crested *Osmunda regalis*, *Athyrium*, *Polystichum*, &c. Mr. C. Sandford was 2d, and Mr. J. Gott, 3d, both having capital collections. In the class for six and three varieties also Mr. Wilkinson was 1st, and the class for three British Ferns, distinct species, brought some charming forms from Messrs. W. Alexander, T. Wilkinson, and J. Gott, the two last being equal 2d.

The other plant classes were somewhat inadequately represented, but it must be borne in mind that the exhibitors about Kendal are amateurs in the strictest sense of the word.

Cut flowers were represented by Roses, Pansies, Stocks, hardy herbaceous plants, which brought *Actæa racemosa*, Greek Valerian, *Thalictrum palmatum*, *Gaillardias*, *Martagon Lilies*, *Orange Lilies*, *Lychnis chalcædonica*, *Phloxes*, *Pentstemons*, annuals, &c. Some boxes of cut Roses not for competition were staged by Messrs. Dickson, Brown & Tait, of Manchester.

Fruit was somewhat sparingly represented; and in the class for eight dishes Mr. C. Sandford was the only exhibitor, having a good lot comprising white and black Grapes, a fine Pine, Peaches, Nectarines, Strawberries, Melons, and Cherries.

Vegetables were plentifully shown in all the classes and generally very good, though the backward, unless season which has prevailed in Westmoreland told sadly against them. A tray of vegetables of twelve varieties, staged by Mr. C. Sandford, was of a superb character throughout, and included Cauliflower, Cabbage, Artichokes, Cucumber, Peas, Longpod Beans, Tomatos, kidney Potatos, Turnips, Carrots, Onions, and Vegetable Marrows.

It is much to be regretted that while the committee appear to do everything in their power to give good prizes for exhibitors, and to take every possible precaution that they shall be properly awarded, that exhibitors who have never been able to take a defeat with equanimity should loudly impugn the judgment of the censors in the exhibition tents, and attribute incapacity and interested motives to the men called in to make the awards. One exhibitor in particular was

most obnoxious, and it unfortunately appears to be an annual failing. The reputations of judges are as nothing to such a person, and he is neither more nor less than an unmitigated nuisance, and should be excluded from competing till he has learned how to behave himself decently at a flower show.

Highgate Horticultural. July 12.—This Society, which stands amongst the most important and prosperous of the many immediately contiguous to the metropolis, has this year eclipsed anything it has previously accomplished both as regards the extent and merits of the different productions generally, of which the exhibition was composed, and what is of equal consequence to the future. The attendance of the public was such as to place the committee in a position to increase and extend the sphere of their exertions. The show was again held in the grounds of Edward Brooke, Esq., Caen Wood Towers, which were unrestrictedly thrown open and were visited by not less than 10,000 people. When once the public find their way to a horticultural exhibition in anything like such numbers as this the success of the Society rests on a firm basis, as the committee have no financial difficulty to contend with—a matter that so often cripples the exertions of even the most energetic promoters. As heretofore, the beautiful position and well-kept garden where the show was held, and the attractive surrounding scenery, which is unequalled within a similar distance of London, had much to do with the attendance, independent of the merits of the show in itself from a horticultural point of view.

The special prizes offered here on this occasion as on previous years, were the greatest source of attraction. Those given by S. Cuming, Esq., for twenty plants, were closely competed for by Mr. Sheen, gr. to E. Brook, Esq., and Mr. Fuller, gr. to E. J. Nettlefold, Esq. Mr. Sheen's group, which was 1st, contained a fine *Stephanotis*, not quite in flower; *Ixora aurantiaca*, *Erythrina cristata-galli*, a large *Dicksonia antarctica*, and *Phoenix humilis*. Mr. Fuller's plants were smaller, but very nicely grown; amongst others he also had a *Stephanotis* in exceptionally good condition—it was the best blooming plant in the show; *Croton majesticus*, and *Dracaena Shepherdii*. Mr. Newman, gr. to W. H. Michael, Esq., 3d. The prize given by E. Brooke, Esq., for twelve plants, six in flower and six fine-leafage, was likewise taken by Mr. Sheen. The Misses Brooke's prizes for six Palms were closely contested—Mr. Ayling, gr. to S. Cuming, Esq., 1st, having excellent plants of *Cocos Weddelliana*, *C. nucifera*, *Dæmonorops palembanicus*, and *Areca lutescens*; 2d, Mr. Fuller. Mr. Brooke's prize for fruit and vegetables, six varieties of each.—1st, Mr. W. Birse, gr. to J. H. Lermite, Esq., who had a meritorious collection. Mr. Brooke's prize for centre-piece of cut flowers.—1st, Miss Bodkin.

The Society's prize for six Orchids was awarded to Mr. Brandrick, gr. to R. France, Esq.; 2d, Mr. Ayling.

Stove and greenhouse Ferns.—These were well shown. 1st, Mr. Sheen; 2d, Mr. Clarke, gr. to Sir Sidney Waterlow. Four stove and greenhouse plants.—1st, Mr. Brandrick; 2d, Mr. Sparkes, gr. to J. W. Jeakes, Esq.

Fine-leaved plants were contributed in quantity, and well done. For six, Mr. Ayling was 1st, having *Anthurium crystallinum* in beautiful condition; 2d, Mr. Brandrick. Four fine-leafage plants.—Mr. Clarke, 1st; Mr. Shepherd, gr. to H. Greening, Esq., 2d.

Caladiums were better shown than usual—stout and well-coloured.—Mr. Fuller 1st, Mr. Brandrick 2d.

Six Zonal Pelargoniums.—These were plentifully produced, and mostly well-flowered; but, as now often seen, the objectionable wire trellises are trained upon were too large and offensively visible. 1st, Mr. Catlin, gr. to Mrs. Lermite; 2d, Mr. Pope, gr. to G. Plucknett, Esq.

Single specimen flowering plant.—1st, Mr. Pope; 2d, Mr. Catlin.

Single specimen foliage plant.—Mr. Fuller was deservedly 1st with a large and beautifully-grown *Toxica superba*; 2d, Mr. Ayling.

The cut flowers were a very nice feature, and forthcoming in sufficient quantities to produce an effect. Twenty-four bunches: 1st, Mr. Taylor; 2d, Mr. Weir; twelve bunches, 1st, Mr. Fuller; 2d, Mr. Ayling.

Twenty-four Roses.—1st, Mr. Eason; 2d, Mr. Silvester, gr. to J. A. Bethell, Esq. Twelve: 1st, Mr. Taylor; 2d, Mr. Shepherd.

Dinner-table decoration, three pieces.—1st, Mr. Winter, gr. to C. Goodall, Esq.; 2d, Mr. Atkins.

Fruit was well exhibited, and in generally good condition. Six dishes.—1st, Mr. Birse. Single Pine.—1st, Mr. Sparkes; 2d, Mr. Pope. Three bunches black Grapes.—1st, Mr. Clarke; 2d, Mr. Silvester. Three bunches white Grapes.—1st, Mr. Brandrick; 2d, Mr. Clarke.

At no place with which we are acquainted is there such inducement held out to cottagers, garden labourers, and mechanics to cultivate their gardens:

in addition to the special prizes offered by the Baroness Burdett Coutts and the Society for well-kept gardens and allotments, there are over fifty classes for vegetables, hardy fruits, and flowers, in which the 1st prizes run from 20s. to 15s. each, and of which there are several, down to from 10s. to 2s. third, besides the children's prizes, with which collectively they amount to over £50. The produce shown under this head of the schedule annually fills a large tent, and is generally of very good quality, and which, independent of any consideration as to the prizes they get at the exhibition, cannot fail to be a substantial benefit to the large number who thus have an additional inducement to spend their spare time profitably. To those who take an interest in such matters the Highgate show is well worth a visit.

STATE OF THE WEATHER AT BLACKHEATH, LONDON, FOR THE WEEK ENDING WEDNESDAY, AUGUST 1, 1877.

July 26.—Overcast, dull, with frequent rain till 11 A.M. Fine and bright after. Cloudless at night.
 — 27.—A fine day, but very cloudy. Cool.
 — 28.—A dull cloudy day.
 — 29.—A very fine hot day.
 — 30.—A fine but rather dull morning till 11 A.M., afterwards fine and bright.
 — 31.—A fine bright and warm morning; very hot and fine afternoon.
 Aug. 1.—A gale of wind during the early morning hours; the day was dull and cool. Overcast at night.

LONDON: Barometer.—During the week ending Saturday, July 28, in the suburbs of London the reading of the barometer at the level of the sea decreased from 29.97 inches at the beginning of the week to 29.53 inches by the night of the 23d, increased to 30 inches by the night of the 25th, decreased to 29.78 inches by the morning of the 26th, increased to 30.17 inches by the morning of the 28th, and was 30.16 inches at the end of the week. The mean reading for the week at sea level was 29.90 inches, being 0.19 inch higher than that of the preceding week, and 0.055 inch below the average.

Temperature.—The highest temperatures of the air observed by day varied from 72° on the 24th and 26th to 65° on the 28th; the mean value for the week was 70°. The lowest temperatures of the air observed by night ranged from 52° on the 28th to 58° on the 23d; the mean for the week was 54°.6. The mean daily range of temperature in the week was 15°, the greatest range in the day was 18°, on the 25th, and the least 10°.9, on the 22d.

The mean daily temperatures of the air, and the departures from their respective averages, were as follows:—22d, 58°.9, -3°.4; 23d, 62°, -0°.2; 24th, 60°.2, -2°; 25th, 60°.1, -2°.1; 26th, 61°.7, -0°.5; 27th, 60°.9, -1°.3; 28th, 56°.9, -5°.3. The mean temperature of the air for the week was 60°.1, being 2°.1 below the average of sixty years' observations.

The highest readings of a thermometer with blackened bulb in vacuo, placed in sun's rays, were 134° on the 25th, 133° on the 26th, and 132° on the 24th; on the 22d the highest reading was 92°. The lowest readings of a thermometer on grass, with its bulb exposed to the sky, was 43°, on the 28th; the mean of the seven low readings was 49°.

Wind.—The direction of the wind was mostly S.W. and W.S.W., and its velocity moderately brisk.

The weather during the week was fine, though generally dull, and the sky generally a little more than one-half cloudy.

Rain fell on three days, the amount collected during the week was 0.62 inch.

ENGLAND: Temperature.—The highest temperatures of the air observed by day were 77° at Sunderland, 75°.1 at Cambridge, and 72°.9 at Sheffield; at Liverpool the highest temperature in the week was 66°.5. The mean value from all stations was 71°.8. The lowest temperatures of the air observed by night were 46° at Truro, 47°.7 at Eccles, and 49° at Wolverhampton; at Portsmouth the lowest temperature was 54°; the mean from all stations was 51°.1. The range of temperature in the week was the greatest at Truro and Cambridge: at both places it was 25°; and the least at Liverpool, 15°.6, and at Portsmouth 16°.3. The mean range from all stations was 20°.7.

The mean of the seven high day temperatures was the highest at Cambridge, 72°.8, and the lowest at Liverpool, 64°.8, and at Plymouth 66°.5; the general mean from all stations was 68°.8. The mean of the seven low night temperatures was the lowest at Eccles, 51°.9, and the highest at Plymouth, 56°.2, and at Portsmouth, 56°; the mean value from all stations was 54°.5. The mean daily range of temperature was the least at Liverpool, 9°.8, and the greatest at Cambridge, 19°.4; the mean daily range from all stations was 14°.3.

The mean temperature of the air for the week from all stations was 59°.9, being 1°.5 lower than the value for the corresponding week in 1876. The highest was 61°.7 at Sunderland, and the lowest 57°.4 at Wolverhampton.

SCOTLAND: Temperature.—The highest temperatures of the air observed by day ranged from 69° at Dundee to 66°.6 at Glasgow; and the mean from all stations was 68°.6. The lowest temperatures of the air observed by night varied from 48° at Dundee to 50° at both Greenock and Perth; the mean value from all stations was 50°.4. The mean range of temperature in the week from all stations was 18°.2.

The mean temperature of the air for the week from all stations was 58°.6, being 1°.3 warmer than the value for the corresponding week in 1876. The highest, 59°.2, occurred at Leith, and the lowest, 57°.8, at Greenock.

Rain.—The amounts of rain measured at the several stations varied from 1.4 inch at Greenock, to 0.3 inch at Dundee; the average fall over the country was 0.6 inch.

DUBLIN.—The highest temperature of the air was 69°.7, the lowest 48°, the range 21°.7, the mean 60°; and the fall of rain 0.45 inch.

JAMES GLAISHER.

Obituary.

MANY gardeners will learn with regret that Mr. JOHN RICHARDS, gr. to Baron Lionel de Rothschild, Gunnersbury Park, Acton, died at Gunnersbury on July 18, at the age of 51, after a severe and wasting illness of some three months' duration. Mr. Richards commenced the profession of a gardener early in life by engaging himself to his uncle, who had a small nursery at Hatton, in Shropshire, and grew plants for market. From Hatton he went to the Botanic Gardens at Birmingham, and, after remaining there for a time, went next to Trentham Gardens, Staffordshire, for a period of nearly three years. On leaving Trentham he went to Shrubland Park, and was plant foreman there for two years, and then filled the post of plant foreman at Woburn Abbey, Beds, the seat of the Duke of Bedford, where he remained for four years. From Woburn he went to Grimston Park, Tadcaster, as gardener to Lord Lodesborough, about the year 1854, and had the charge of the Grimston Gardens for the space of fourteen years. While there he made a great reputation as a cultivator and exhibitor of stove and greenhouse plants and Orchids at the York and other shows in the North of England. In 1868 Mr. Richards left Grimston, and took charge of the gardens at Stoke Park, Slough, the residence of E. J. Coleman, Esq., and after remaining there for the space of sixteen months was offered and accepted the charge of the gardens at Gunnersbury Park, where he remained till his death—a period of nearly seven years. Under his care the gardens at Gunnersbury maintained their old reputation, and at a meeting of the Royal Horticultural Society about three years ago Mr. Richards was awarded the Lindley Medal for some superb examples of *Odontoglossum vexillarium*.

He was buried at the cemetery, Ealing, on July 21, which is immediately contiguous to Ealing Park, formerly the residence of Mrs. Lawrence, of such fame as a cultivator and exhibitor of plants. R. D.

Natural History.

SEASON TICKET.—It may be interesting to some of your readers to be informed that on a small piece of frame-work underneath a third-class smoking carriage on the London and South-Western Railway a water-wagtail has built her nest and reared a young and thriving family of four. The train runs regularly from Cosham to Havant five times a day, in all about 40 miles, and the station-master informs me that during the absence of the train the male bird keeps close to the spot waiting with manifest interest and anxiety the return of his family from their periodical tours. R. E. D., East Cosham, Hants, in the "Times."

Answers to Correspondents.

ARAUCARIA EXCELSA GLAUCA: E. N. Phillips. This is not a hardy plant, and therefore ought not to have disqualified a collection of greenhouse plants in which it was shown. As to its being alleged to be "not a plant but a tree," that is a mere quibble. Are not all trees plants? It is certainly not hardy in the climate of London.

BALSAMS: A. Dean. A fine strain of Balsams, distinct in character from some other fine lots which have recently been exhibited. They are remarkable for the large size and doubleness of their flowers, the variety of their colours, and the dwarfness of their habit.

BOWLING GREEN: Bowler. We cannot tell the exact state of your bowling green from the description. If only "slightly uneven" you might fill up the hollow places with fine earth, dressing off carefully to the general level, and possibly the grass would grow up through the new soil, or if not these places could be re-sown in spring. If you keep it well cut in the growing season that will check the Clover. The roller will not be too heavy if not used when the ground is excessively wet.

EXHIBITORS: J. Sharo. We reply to your queries as follows:—1. If a man, not being a professional, but constantly employed by a gentleman to attend to a small garden and greenhouse with frames, &c., should wish to compete, in what class should he be placed? In the gardeners' class; he is to all intents and purposes the gardener to the gentleman employing him. 2. If a man, not a professional, has a large garden and greenhouse, and grows pot plants, fruits, flowers and vegetables for market, also keeps a small shop and sells seeds and other garden requisites, in what class should we place him, should he wish to compete? Being a dealer, he would go into the nurserymen's class. We should add that our replies are based on the supposition that your schedule recognises the usual distinctions of nurserymen, gentlemen's gardeners, and cottagers, but you have given us no information on this point.

FITTONIAS: Herbaceous Acanthaceae. Stove plants propagated by cuttings.

HERBACEOUS PLANTS: Herbaceous. Anything reported to be hardy should grow in such a locality. See what your neighbours grow.

HOLLYHOCKS: A. D. The leaves are infested with the Mallow Fungus (Puccinia malvacearum). Burn the plants at once.

INSECTS: R. E. S. H. Julus terrestris. Try Potato-traps—viz., slices of Potatoes put down near the plants to attract the insects; but we know of no remedy. A. M.—M. Y. The larva of a sawfly named Lyda clypeata. A. M.

INSECTS ON WHEAT: L. H. G. The insect doing the mischief is Aphis cerealis (the Wheat Greenfly). Of course it will do a great deal of mischief to the crop, and no topical application to a Wheat crop nearly ripe is possible; but it is just such a case as I have lately advocated for a temporary cessation of the crop throughout the district. Andrew Murray.

NAMES OF PLANTS: J. F. A magnificent specimen of Ammi majus.—P. Middleton. Probably Crinum ornatum, but the flowers were so rotten when they reached us that we cannot be certain.—J. M. Probably Achimenes coccinea. Send again when in flower.—W. P. Syringa Emodi.—T. R. B. Datura Stramonium.—J. M. The shrub is Calycanthus occidentalis.—John Leman. Cotoneaster vacillaris.—F. 1. Linaria sp., specimen insufficient; 2. Spirea filipendula flore-pleno; 3. Sedum album. The fungus is not a Truffle, but a small Puff-ball, Lycoperdon.—Z. Y. A. Epidendrum ciliare.—W. Geddes. 1. Campanula persicifolia, herbaceous; 2. Geum chilense; 3. Potentilla nepalensis var.; 4. Campanula latifolia; 5. C. carpatica; 6. Sisyrinchium Bermudicum.—J. M., Falmouth. The parasite growing on the Gorse is the Common Dodder (Cuscuta europæa).—W. D. F. Doodia caudata.—A. F. 1. Hypericum quadrangulum; 2. Galeopsis Tetrahit; 3. Teucrium Scorodarium.

PEA: T. J. & Sons. Probably Superlative. Compare the growing plant with the published description, as we cannot be certain from a single pod.

PEARS: H. & W. Your Pears are suffering from a complication of disorders. First a little four-legged Acarus attacked the leaves, then there was an extra growth of the hairs, and finally they were attacked by a fungus, Helminthosporium pyrorum. The spores of the fungus are so numerous, and the Acarus so minute, that it seems almost impossible to extirpate them. The fungus sometimes attacks the blossoms. M. J. B.

ROSES: Miss P.—Do not remove the infected leaves,

but by sprinkling sulphur over them, or syringing with Gishurst Compound, neutralise existing evil. Have a good layer of thoroughly decomposed manure well forked in amongst the roots next January, adding, if possible, a little lime; or, better still, superphosphate of lime. If your stiff soil is deep, and the instructions as to manuring are attended to, the need for artificial waterings should not occur.

TWIN CUCUMBERS: C. J. G. The fusion of two flowers and ultimately of two fruits is by no means of rare occurrence.

VINE LEAF: S. No. There is not a trace of the Phylloxera, the warts on the under side resulting, no doubt, from the causes you mention.

* * * Correspondents are specially requested to address, post-paid, all communications intended for publication to the "Editors," and not to any member of the staff personally. The Editors would also be obliged by such communications being sent as early in the week as possible. Correspondents sending newspapers should be careful to mark the paragraphs they wish us to see. Letters relating to Advertisements, or to the supply of the Paper, should be addressed to the Publisher, and not to the Editors.

CATALOGUES RECEIVED.—Charles Turner (Slough), Catalogue of Strawberry Runners for Autumn and Spring Planting.—Vilmorin-Andrieux & Co. (4, Quai de la Mégisserie, Paris), Catalogues of Flower Seeds, Bulbous Plants, and Strawberries.

COMMUNICATIONS RECEIVED.—Dicksons & Co. (with many thanks)—D. T. F. 1, 2, 3 distributed; with many thanks. We will bear in mind what you say.—E. W. C.—E. W.—J. W. (next week)—J. J.—J. C. & Co.—C. C.—Cyuro.—W. D.—A. W.—H. E.—J. H. K.—C. Y. M.—H. G.—J. L.—W. E.—J. W. S.—R. P.—G. Cooling.

DIED, at Bath Lodge, Luckenham Park, Chippenham, Wiltshire, on July 12, WILLIAM GEORGE, gardener and forester (a native of Orton, Morayshire), aged 74.

Markets.

COVENT GARDEN, August 2.

The London season being now over, all kinds of hot-house fruits are considerably lower, Melons alone being inquired after. Nearly all the soft fruit has come to market, and buyers are pretty well filled up, but the demand for black Currants and Raspberries still keeps good. James Webber, Wholesale Apple Market.

FRUIT.

Table with 3 columns: Fruit name, quantity, and price. Includes Apples, Apricots, Cherries, Currants, Grapes, Lemons, Melons, Oranges, Peaches, Pears, Pine-apples, Strawberries, Figs.

VEGETABLES.

Table with 3 columns: Vegetable name, quantity, and price. Includes Artichokes, Aubergines, Beans, Beet, Cabbages, Carrots, Cauliflowers, Celery, Chilis, Cucumbers, Endive, Batavia, Garlic, Gooseberries, Herbs, Horse Radish, Leeks, Potatoes, Lettuce, Mint, Mushrooms, Onions, Parsley, Peas, Radishes, Spanish, Rhubarb, Salsify, Shallots, Spinach, Tomatos, Turnips, Vegetable Marrows.

PLANTS IN POTS.

Table with 3 columns: Plant name, quantity, and price. Includes Balsams, Bedding-out plants, Begonias, Bouvardias, Calceolarias, Clematis, Cockscombs, Coleus, Cyperus, Dracena terminalis, Ficus elastica, Fuchsias, Heaths, Heliotrope, Hydrangea, Liliums, Mignonette, Myrtles, Palms, Pelargoniums, Petunias, Rhodanthe, Roses, Valotta purpur.

CUT FLOWERS.

Table with 3 columns: Flower name, quantity, and price. Includes Bouvardias, Calceolarias, Carnations, Cornflower, Eschscholtzia, Eucharis, Gardenia, Heartsease, Heliotropes, Lilies, Mignonette, Myosotis, Pelargoniums, Primula, Rocket, Roses, Stephanotis, Sweet Peas, Sweet Sultan, Tropæolum.

SEEDS.

LONDON: August 1.—The seed markets this week have shown a good seasonable attendance of buyers, and there has been a fair trade doing. For sowing white Mustard seed, in particular, there has been a brisk demand, under which the already scanty stocks of 1876 seed have been further materially reduced, and in fact nearly cleared off. New Rape of fine quality is now in slightly improved supply—values exhibit considerable steadiness, the yield having proved very disappointing. One or two handsome samples of new English Winter Tares have arrived on Mark Lane; but for these, as well as for Rye, prices are not yet definitely fixed. Trefoils, owing to the uniformly unfavourable reports of the new crop, continue to be very strongly held; occasionally a few parcels of yearling seed have changed hands at a heavy advance, but holders generally appear resolved to await the probability of a higher range of quotations rather than quit on present terms. There is also a better feeling as regards white Clover seed. For Trifolium incarnatum last week's currencies are well maintained; at the comparatively unremunerative rates now prevailing there is no great inducement for farmers to market their produce, consequently the supply to hand keeps in narrow compass, and a firm tone characterises the article. We have a good inquiry for Swede seed of the new crop. John Shaw & Sons, Seed Merchants, 37, Mark Lane, London, E.C.

CORN.

At Mark Lane on Monday trade as regards Wheat was extremely heavy. English produce was 1s. to 2s. per quarter cheaper, while a similar decline may be quoted with respect to foreign. Some new Wheat grown at Headcorn, in Kent, was shown on the market, and as an illustration of what the season is likely to prove in point of quality it may be mentioned that its weight was equal to fully 52 lb. per bushel, while the total growth averaged about six quarters per acre. Barley was about 6d. dearer on the week. Malt was quiet, on former terms. In Oats certain descriptions retained an advance of from 6d. to 1s. upon the quotations of this day week. The same observations apply to Maize. Beans and peas were dull, at about late rates. Flour was heavy, all transactions being at less money. On Wednesday the Wheat market, under the influence of fine weather, was heavy, and any pressure to sell was accompanied with a marked reduction in price. Spring corn was comparatively steady, although in Barley and Oats transactions now and then occurred at rather less money. Flour followed the movement of Wheat.—Average prices of corn for the week ending July 28:—Wheat, 64s. 6d.; Barley, 39s.; Oats, 27s. 10d. For the corresponding week last year:—Wheat, 47s. 5d.; Barley, 31s. 4d.; Oats, 31s. 2d.

CATTLE.

At the Metropolitan Market on Monday there was a short supply of beasts, and prices were for the most part the same as on Monday s'mnight. Sheep also were in short supply; trade was not very brisk for them, yet there was no change in price. Choice lambs were in demand, but other kinds were a heavy trade. The few calves on offer made a fair price. Quotations:—Beasts, 4s. 6d. to 5s. 2d., and 5s. 3d. to 6s. 2d.; calves, 5s. to 6s. 2d.; sheep, 5s. 6d., to 6s., and 6s. 4d. to 7s.; lambs, 7s. to 8s.; and pigs, 4s. to 5s.—On Thursday trade ruled quiet, and without special feature. There was a moderate supply of beasts on offer. The demand was hardly so firm, at drooping prices. Sheep were quiet, but tolerably steady. Lambs sold at late rates. Calves and pigs were quiet.

HAY.

At Whitechapel on Monday good old fodder was firm, but there was not much trade for inferior and new. Prime clover, 100s. to 140s.; inferior, 85s. to 95s.; good new clover, 100s. to 120s.; prime meadow hay, 90s. to 124s.; inferior, 70s. to 85s.; new hay, 80s. to 100s.; and straw, 44s. to 60s. per load.—On Thursday there was a fair supply of fodder. Trade was good, and prices were firm. Quotations:—Clover, prime old, 100s. to 140s.; inferior, 85s. to 95s.; good new, 100s. to 126s.; hay, prime old, 90s. to 124s.; inferior, 70s. to 85s.; good new, 80s. to 100s.; and straw, 44s. to 60s. per load.—Superior old meadow hay, 128s. to 136s.; inferior, 90s. to 112s.; new hay, 90s. to 112s.; superior old Clover, 132s. to 140s.; inferior, 110s. to 117s.; new Clover, 90s. to 112s.; and straw, 53s. to 63s. per load.

POTATOS.

The Borough and Spitalfields reports state that the supplies of Potatoes are moderate, and trade remains steady. Kent Regents, 140s. to 180s.; Essex do., 130s. to 160s.; Kent shaws, 120s. to 140s.; Essex do., 120s. to 150s.; kidneys, 160s. to 200s.; Early Rose, 120s. to 160s. per ton.—The imports into London last week comprised 1766 baskets from Rotterdam, 333 packages 394 baskets Antwerp, 104 packages 103 barrels Hamburg, 129 baskets 52 sacks 37 packages Boulogne, 193 baskets Bremen, 54 casks Dunkirk, and 12 packages Palermo.

COALS.

The prices obtained at Wednesday's market indicate an advance on those current on Monday. The quotations were:—Wylam, 17s.; Holywell Main, 17s.; Walls End—Hawthorn, 20s.; Hutton, 20s.; Hutton Lyons, 18s. 3d.; Haswell, 18s. 3d.; Lambton, 19s. 6d.; Seaton, 17s.; South Hutton, 20s.; Tunstall, 18s. 3d.; Chilton, 18s. 3d.; Kelloe, 18s. 3d.; East Hartlepool 19s. 9d.; South Hartlepool, 18s. 3d.; Tees, 19s. 9d.

HENRY ORMSON,

HORTICULTURAL BUILDER, AND HOT-WATER APPARATUS ENGINEER.

THE BEST BUILT HOTHOUSES, CONSERVATORIES, &c., AT THE LOWEST PRICES.

Plans and Estimates given for Horticultural Buildings of every description, either in Wood or Iron.

H. ORMSON'S WORK, on an extensive scale, both Building and Heating, may be seen at the Royal Gardens, Kew, and at many of the Seats of the Nobility and Gentry throughout the Country.

PLAIN AND INEXPENSIVE HOTHOUSES

Designed and Built with a strict regard to Economy in Price, the best of Materials and Workmanship, and Practical Adaptation.

Unsurpassed Boilers and Heating Apparatus erected and fitted in all parts of the Kingdom.

Surveys made and Gentlemen waited on in any part of the country. Plans and Estimates on application. Tenders for Drawings prepared by Architects.

ILLUSTRATED CATALOGUES ON APPLICATION.

HENRY ORMSON,

HORTICULTURAL BUILDER, AND HOT-WATER APPARATUS ENGINEER,

STANLEY BRIDGE, KING'S ROAD, CHELSEA, LONDON, S.W.

In consequence of the increasing demand for Conservatories, in which pure art is combined with moderate cost, T. H. P. DENNIS & Co. have been led to introduce designs of a character hitherto unknown. One of these designs, showing a house 22 feet 6 inches X 13 feet 6 inches, is annexed, and the result, as regards the extremely low price (which includes fixing, glazing, painting, carriage, &c.), has been attained only by special machinery and a system of interchangeable parts.

T. H. P. DENNIS & Co. are also prepared to provide and fix Hot-water Heating Apparatus and Horticultural Buildings of any dimension or description.

Full-sized specimens of Greenhouses, &c. and Hot-water Apparatus in work, can be inspected at Mansion House Buildings, London, E.C.

Gentlemen waited upon at their residences by experienced designers.

Estimates and Plans free.

PARHAM'S PATENT SYSTEM OF GLAZING WITHOUT PUTTY ON CHANNELLED WROUGHT-IRON OR RED DEAL RAFTERS,

secures almost entire immunity from Breakage of Glass, extreme facility for Repairs, and absolute freedom from Drip.

WILLIAM PARHAM,

Horticultural Builder and Hot-water Engineer,

NORTHGATE WORKS, BATH;
AND
280, Oxford Street, London, W.

* * * Specimen Houses, Frames, &c., and Drawings of important Works which W. P. has carried out may be seen at either address.

ILLUSTRATED CATALOGUES
and PRICE LISTS free.

Designs and Estimates prepared free of charge for Horticultural Buildings and Hot-water Works of any magnitude.

New "Registered" Acme Plant Preserver,

With "Truss" Hinge, and no Principals.

The Ridge always fits close, the interior is free from all obstruction, the corners are secured in iron angle plates: 21-oz. glass.

Extra Strong Cucumber or Melon Frames,

With 2-inch sashes and 1 1/2-inch red deal frames, secured at each corner with two wrought-iron strap bolts. Glazed, without putty, with 21-oz. glass.

GEO. WHEELER, NURSERYMAN, SEEDSMAN and FLORIST, Warminster, Wilts.

CALCEOLARIA.—Geo. Wheeler's Superb Strain, being in habit very compact, stout, and dwarf, of great variety in colour, and beautifully marked. Is inferior to none. Retail packets, 2s. 6d., 1s. 6d. and 1s. each. Trade packets, 21s. to 5s. each.

G. W. distributed his first raised hybrid Calceolaria in 1830, at 2s. each in trade; and in 1832 supplied many sorts of 6 plants each to the trade at 4s. the set.

IMPERIAL CABBAGE.—G. Wheeler's Improved Genuine, after a test of about half a century, still maintains its character of first-rate Early. A limited quantity still on hand at the rate of 1s. 2d. per ounce.

Prepaid Orders for the above will be sent post-free.

H. CANNELL begs to inform his Customers, Friends, and the Public generally that his **AUTUMN CATALOGUE** of all the New Soft-wooded Plants and the best older varieties is now ready, and will be sent post-free. H. C. wishes to draw particular attention to his 250 varieties of **ROSE BUDS**, cuttings of his unrivalled collection of *Ceraniums*, *Verbenas*, *Fuchsias*, *Coleus*, *Petunias*, *Lobelias*, *Lantanas*, *Dahlias*, *Chrysanthemums*, *Primulas*, *Pansies*, *Violas*, &c., all of which are supplied at this season very cheaply, and many thousands of Seedling *Primulas*, *Cinerarias*, 1s. 6d. per dozen, are now also ready to be posted off.

Swanley, Kent.

Fibrous Peat for Orchids, &c.

BROWN FIBROUS PEAT, best quality for Orchids, Stove Plants, &c., 1/6 6s. per truck. **BLACK FIBROUS PEAT**, for *Rhododendrons*, *Azaleas*, *Heaths*, *American Plant Beds*, 17s. per ton.

Delivered on rail at Blackwater, S. E. R., or Farnborough, S. W. R., by the truck-load. Sample sack, 5s. 6d. each. Fresh **SPHAGNUM**, 10s. 6d. per sack.

WALKER AND CO., Farnborough Station, Hants.

GISHURST COMPOUND.—Used by many of the leading Gardeners since 1859, against Red Spider, Mildew, Thrips, Greenfly, and other Blight in solutions of from 1 to 2 ounces to the gallon of soft water, and of from 4 to 16 ounces as a winter dressing for Vines and Fruit Trees. Has outlived many preparations intended to supersede it.

Sold Retail by Seedsmen, in Boxes, 1s., 3s., and 10s. 6d. Wholesale by **PRICE'S PATENT CANDLE COMPANY** Limited.

SIMPSON'S RED SPIDER, THRIPS, &c., ANTIDOTE. Testimonials of the highest order on application. Per quart, condensed, 6s.; per pint, 3s. 6d. Supplied to Seedsmen and Chemists. Strongly recommended in the *Gardener*, and by many first-class Gardeners.

Prepared by JOHN KILNER, Wortley, near Sheffield.

SCOTT'S WASP DESTROYER.—The only preparation made for thoroughly destroying Wasps, large Flies, &c. Sold in bottles, at 1s. 6d., 2s. 6d. and 5s. each. The larger sizes are the cheapest. May be obtained through any Seedsmen, or direct from

JOHN SCOTT, The Royal Seed Stores, Yeovil.

TEBBS' UNIVERSAL FUMIGATOR,

For Greenhouses, Conservatories, Ferneries, Frames, Poultry Houses, Infirmarys, Ships, Bed-rooms, &c.

This cheap and thoroughly effective Fumigator requires no attention when once lit, no fear of flaming, no waste of material, every particle being given off in dense smoke.

Testimonial.—"I shall never think of using pots again."

Price 3s., large size 4s. 6d. each. Wholesale and Retail of **FLANAGAN AND SON**, Seedsmen, 98, Cheapside, London, E. C.

And Wholesale of **CORRY AND SOPER**, Shad Thames, London, S. E.

F. ROSHER AND CO., Brick and Tile Merchants. See addresses above.

SILVER SAND, fine or coarse grain as desired. Prices by Post per Ton or Truck-load, on Wharf in London, or delivered direct from Pits to any Railway Station. Samples of Sand free by post.

FLINTS and BRICK BURRS for Rockeries or Ferneries. **KENT PEATS** or **LOAM** supplied at lowest rates in any quantities.

F. ROSHER AND CO.—Addresses see above. N. B.—Orders promptly executed by Rail or to Wharves. A liberal Discount to the Trade.

NETTING FOR FRUIT TREES, SEED BEDS, RIPE STRAWBERRIES, &c.

TANNED NETTING for protecting the above from Frost, Blight, Birds, &c., 2 yards wide, 3d. per yard, or 100 yards, 20s.; 4 yards wide, 6d. per yard, or 50 yards, 20s.

NEW TANNED NETTING, suited for any of the above purposes, or as a Fence for Fowls, 2 yards wide, 6d. per yard; 4 yards wide, 1s. per yard; 1/2-inch mesh, 4 yards wide, 1s. 6d. per yard. **TIFANY**, 6s. 6d. and 7s. 6d. per piece of 20 yards.

EATON and DELLER, 6 & 7, Crooked Lane, London Bridge.

THOMAS'S NEW POULTRY FENCING,

No. 508.

Very strong and durable. Reduced Prices, 1877.

Galvanised after Manufacture, with Iron Standards, Painted Black, and SPACED 2 FEET APART, rendering it the strongest and best Fence in the Market.

This ornamental Fencing is easily fixed or removed by any labourer, without extra cost.

PRICES.—6 feet high, 6s. per yard; 7 feet high, 7s. per yard, Including the Iron Standards and the Bolts and Nuts for securing the Panels to the Standards. Doors are charged 3s. extra, except when 12 yards are ordered, in which case a door is included.

Five per cent. discount allowed for prompt cash on Orders amounting to 40s. and upwards.

Illustrated and Priced Catalogues of every description of Horticultural Wirework on application.

J. J. THOMAS & CO., PADDINGTON WIREWORKS, 285 and 362, EDGWARE ROAD, LONDON, W.

SHAW'S TIFFANY, ELASTIC NETTING, CANVAS, &c., for Shading, Protecting, and other Horticultural Purposes. For Samples and Prices apply to JOHN SHAW AND CO., 29, Oxford Street, Manchester.

Established over a Quarter of a Century.

Is in use over many thousand miles, And has been awarded the Medals and highest Commendation of all the leading Agricultural Societies.

It is constructed with POWERFUL WINDING STRAINING PILLARS, RIGID INTERMEDIATE IRON POSTS, STRONG and DURABLE WIRE CABLE STRANDS, Forming the most efficient Strained Iron Fencing known for agricultural and general purposes.

Continuous Bar Iron Fencing.

With bars secured by F. M. & Co.'s Patent Self-locking Joints, which effectually prevent the uprights being pushed aside, and are independent of loose pins, wedges, or staples.

IRON ENTRANCE and FIELD GATES, IN WROUGHT AND CAST IRON.

Designed for the Mansion, Villa, or Farm, **WICKET AND GARDEN GATES,** In Great Variety of Patterns.

Iron Hurdles, Railing, Tree Guards, **FRUIT ESPALIERS, WALL FRUIT TRAINERS, &c.** Illustrated and Described in F. M. & Co.'s New Catalogue, sent on application.

IMPROVED LIGHTNING CONDUCTORS, With fittings complete, simple in construction, and easily erected by a careful mechanic.

Oil Paint No Longer Necessary.

HILL AND SMITH'S BLACK VARNISH for Preserving Ironwork, Wood, or Stone. This Varnish is an excellent substitute for oil paint on all outdoor work, while it is fully two-thirds cheaper. It was introduced upwards of thirty years ago by the advertisers, and its genuine good quality, notwithstanding a host of unprincipled imitators, is fully attested by its constantly increasing sale. It may be applied by an ordinary labourer, requires no mixing or thinning, and is used cold. It is used in the grounds at Windsor Castle, Kew Gardens, and at the seats of many hundreds of the Nobility and Gentry, from whom the most flattering testimonials have been received, which HILL & SMITH will forward on application.

Sold in casks of about 30 gallons each, at 1s. 6d. per gallon, at the Manufactory, or 1s. 8d. per gallon carriage paid to any Station in the Kingdom.

UNSOLICITED TESTIMONIAL RECEIVED MAY 3, 1877. "The *Chronicle*, Alderly Edge, Manchester.—Messrs. Hill & Smith.—Sir,—For some 20 years I have used your 'Black Varnish,' and shall be glad if you will forward me another cask, as I consider it the best thing known for the preservation of all outdoor work, either wood or iron, that requires to be painted. —Yours respectfully, ALFRED LOWE, J.P."

Apply to HILL and SMITH, Brierley Hill Ironworks, near Dudley; and 118, Queen Victoria Street, London, E.C., from whom only it can be obtained.

CAUTION.—It having lately come to the knowledge of HILL & SMITH that spurious imitations of this Varnish are being offered by unprincipled dealers at a slight reduction in price, they would especially draw attention to the fact that every cask of their Varnish is legibly marked with their name and address, without which none is genuine.

CARSONS' PAINT,

PATRONISED BY THE QUEEN, H.R.H. THE PRINCE OF WALES, H.R.H. THE DUKE OF EDINBURGH, The British, Indian and Colonial Governments, 10,000 of the Nobility, Gentry, and Clergy, Railway and Canal Companies, Collieries, Ironmasters, &c., &c.,

JOSEPH BRANHAM, HORTICULTURAL and HOT-WATER ENGINEER, WIRE WORKER, WEAVER, &c., 104, Dale Street, and 41, Elizabeth Street, Liverpool. J. B. strongly recommends the ALLERTON PRIORY BOILER as one of the most powerful for extensive work. He has fixed one capable of heating 10,000 feet of 4-inch piping. See *Gardeners' Chronicle*, p. 647. Also a WELDED WROUGHT IRON WATERWAY BACK for ordinary Saddle Boilers. These Backs can be fixed to any Boiler now in use, and are a great saving in fuel and labour. He is also prepared to fix any kind of Boiler made. Manufacturer of the Registered LIVER FRONT for large Boilers, IRON and WIRE WORK in all branches. References from Noblemen and Gentlemen for work done. Plans and Estimates given.

For Sale, a STEVENS' IMPROVED TRENTHAM WROUGHT IRON HORTICULTURAL BOILER, 6 feet long by 3 feet diameter, fitted with Inlet and two Outlet Pipes, Fire-door and Grate complete. For price and particulars apply to HILL AND SMITH, Brierley Hill Ironworks, Dudley.

SILVER MEDAL

AWARDED AT Birmingham Meeting, Royal Agricultural Society, 1876.

1876.

HIGHEST HONOR

AT THE Centennial Exhibition, Philadelphia.

Specially adapted for Pumping in Gentlemen's Houses and Grounds. No Labor Required.

HAYWARD TYLER & Co., 84, WHITECROSS STREET, LONDON.

CRITCHLEY'S PATENT HEAT REGULATOR,

AN APPARATUS FOR REGULATING THE HEAT IN HORTICULTURAL BUILDINGS.

A, Iron Box fitted up water-tight. B, Pipe or Supply of Water from Boiler. C, D, Pipes for Circulating Hot Water. E, F, Pipes for Return of Water to Iron Box. G, Pipe for Returning Water to Boiler. H, I, J, K, Piston-Rods for Opening and Closing Valves.

The advantages of these Regulators are that houses may be kept at different degrees of heat, or the circulation of water and heat entirely stopped in one part and not in others. They may be fitted with as many valves as required, and are particularly adapted for forcing houses where top and bottom heat is used. They may be fixed in any part of the apparatus most suitable for working, without regard to the position of the Boiler.

The following Testimonial has been received:—

"Berkeley Castle, April 13, 1875. 'Gentlemen,—I am happy to inform you, now that the late severe winter is past, that the Hot Water Apparatus erected by you does its work to my entire satisfaction. As to the two Heat Regulators, which represent thirty valves, I have had ample opportunities of practically proving them, and unhesitatingly admit they are far superior to any other valve; in fact, I think it the greatest improvement that has come out for horticultural purposes.'

"I am, Gentlemen, yours truly, 'R. H. CRONK, 'Gardener to the Right Hon. Lord Fitzhardinge.' Estimates and Plans furnished for Warming Gentlemen's Mansions and Public Buildings. Orders attended to in any part of the kingdom, and guaranteed to answer their intended purposes. Prospectus and Price Lists post-free.

Messrs. CRITCHLEY & CO., Horticultural Engineers and Builders, GROSVENOR WORKS, CHELTENHAM.

STEVENS' TRENTHAM GREENHOUSE BOILER,

After long experience, has proved the most SIMPLE, ECONOMICAL, EFFECTUAL, and LASTING BOILER extant; recently improved. For Illustrations, with full particulars, apply to the Sole Makers.

F. & J. SILVESTER, HOT-WATER ENGINEERS, &c., &c. Castle Hill Works, Newcastle, Staffordshire.

Our Boilers are the ONLY ones made with the sanction and under the inspection of the inventor, Mr. Stevens—all others being base imitations.

LONDON AND COUNTY BANKING COMPANY.

Established in 1836, and Incorporated in 1874 under "The Companies' Act, 1862."

SUBSCRIBED CAPITAL—£3,750,000, in 75,000 Shares of £50 each.

REPORT ADOPTED at the HALF-YEARLY GENERAL MEETING, August 2, 1877.

FREDERICK FRANCIS, Esq., in the Chair.

The Directors, in presenting to the Proprietors the Balance-Sheet of the Bank for the Half-Year ended the 30th June last, have the satisfaction to report that, after paying interest to Customers and all charges, allowing for Rebate, and making provision for Bad and Doubtful Debts, the Nett Profits amount to £122,889 11s. 10d. This sum, added to £11,166 8s. 3d. brought forward from the last account, produces a total of £134,056 0s. 1d.

They have declared an Interim Dividend for the Half-Year at the rate of 16 per cent. per annum, which will absorb £120,000, leaving a balance of £14,056 0s. 1d. to be carried forward to Profit and Loss New Account.

The Dividend, £1 12s. per share, free of Income Tax, will be payable at the Head Office, or at any of the Branches, on or after Monday, 13th instant.

BALANCE SHEET OF THE LONDON AND COUNTY BANKING COMPANY, JUNE 30, 1877.

Table with columns Dr. and Cr., listing various financial items like Capital paid up, Reserve Fund, and Profit and Loss.

Table with columns Dr. and Cr., listing various financial items like Cash on hand, Investments, and Freehold Premises.

Table with columns Dr. and Cr., listing various financial items like Profit and Loss Account, Expenses, and Balance carried forward.

We, the undersigned, have examined the foregoing Balance Sheet, and have found the same to be correct. (Signed) MUNGO McGEORGE, WILLIAM NORMAN, RICHARD H. SWAINE, } Auditors.

London and County Banking Company. NOTICE IS HEREBY GIVEN that a DIVIDEND on the CAPITAL of the COMPANY, at the rate of 8 per cent. for the Half-year ended June 30, 1877, will be PAYABLE to the Proprietors, either at the Head Office, 21, Lombard Street, or at any of the Company's Branches, on or after MONDAY, the 13th instant.

PVNAERT, at the Chief Post-office, Ghent.

ADVERTISERS are requested to note that although we do not object to receive Letters to be called for, we cannot undertake to forward them.

PARTNERSHIP.—A Nurseryman, carrying on a successful business within 25 miles of London, is desirous of meeting with a Partner. Falling health causes Advertiser to wish to find a man, or men who in, say, one or two years would be able to take over from him the entire business. Money would be required, but every facility be afforded provided substantial guarantees were given. The fullest references given and required.—Advertiser by letter, giving outline of mess and position. NURSERYMAN, Messrs. Norris, Allens & Carter, Solicitors, 20, Bedford Row, London, W.C.

WANTED, about the last week in August, a HEAD WORKING GARDENER, where an Under Gardener is kept and other assistance given; must understand Flower and Kitchen Gardening, Vines, Wall Fruit, and Houses. Cottage found.—C. GORDON, Newtimber Place, Hurstpierpoint.

WANTED (10 miles from Town), a respectable and industrious Married Couple, the Man as HEAD WORKING GARDENER—must thoroughly understand every branch of the profession, including Forcing—the Wife to undertake the entire Laundry of a large family, all washing materials found. Letters must state full particulars and wages required, or will not be answered.—F. P., Forest House, Chigwell, Essex.

WANTED, in Yorkshire, a thorough good industrious GARDENER. He would have the entire Management and Working of the Houses. Assistance given for outside work. Must be well up in Vines and Fruit Growing. Preference given to a total abstainer, and one whose Wife could make herself useful if required. Must have first-class references from last and previous situations. Wages 30s. a week and cottage.—A. B., care of Messrs. VEITCH and SON, Chelsea, London, S.W.

WANTED, a SINGLE-HANDED GARDENER (OUTDOOR), married, understanding Pine, Peach, and Grape Houses.—Mr. BAKER, 61, New Street, Birmingham.

WANTED, a strong, active young Man, as UNDER GARDENER, who has some knowledge of and will take an interest in Flowers under Glass, &c. and willing to make himself useful in Kitchen and Fruit Garden.—Apply by letter only, stating wages and experience, to Mr. PAINE, Cedar House, Stamford Hill, London, N.

WANTED, 12 miles from London, a Man and Wife (between 30 and 40 years of age), without incumbrance—the Man as COACHMAN and GARDENER, and to make himself generally useful, the Wife as LAUNDRESS, and to take charge of a small furnished house adjoining that of the Advertiser. Wages 30s. a week, furnished rooms, coals, and gas found.—Apply by letter, to Mr. G., care of Mr. J. W. Vickers, General Advertising Offices, Nicholas Lane, Lombard Street, E.C.

Propagator of Roses, Rhododendrons, &c. PAUL and SON want a clever, experienced Man, as Propagator (Indoors) of Roses, General Hardy Stuff, and Soft-wooded Plants. Efficient help and every encouragement given to a really painstaking Man.—Apply, by letter, to The Old Nurseries, Cheshunt, N.

Propagator of Roses, &c. W. B. ROWE is in want of a thoroughly experienced (Indoors) Propagator of Roses, and Hard and Soft-wooded Stuff. He must be well up in this department, and to a clever, good man it will be a most comfortable and permanent situation. Salary not so much an object as an experienced man and one who studies his employer.—Address, stating age, qualifications, salary required, &c., to Barbourne Nurseries, Worcester.

WANTED, in an old-established Seed Warehouse in the City, a competent and trustworthy Man as HEAD SHOPMAN; he must be of good address and a first-class Salesman, also thoroughly conversant in all branches of the Seed and Plant Trade for Home and Export.—Apply, by letter, with full particulars, to A. E., 32, Aldermanbury, London, E.C.

WANTED, a JUNIOR ASSISTANT, with some knowledge of the Trade, for a Provincial Seed Establishment. Must be well disposed and of good address.—Apply, stating particulars, in own writing, to GEO. P. DARBY, Hertfordshire Seed Establishment, Watford.

Seed Trade.

WANTED, an intelligent, respectable young MAN, with some experience, in a small Retail Shop, and to make out Invoices, &c.—State age, reference, and wages, to JAMES BIRD, Nurseryman, Downham.

WANTED, as COWMAN, on a Nobleman's Estate, a steady, industrious Man, about thirty years of age, to take the care of Dairy Cows, Milk, &c., Pigs, and rear a number of Calves in the year. This to a really good man would prove a most comfortable place. None need apply but those who are fully competent, with good characters.—H. HEPBURN, Estate Bailiff, Scarisbrick Hall, Ormskirk.

WANT PLACES.**Head Gardeners.**

JOHN LAING AND CO. can at present recommend with every confidence several energetic and practical Men, of tested ability and first-rate character. Ladies and Gentlemen in WANT of GARDENERS and BAILIFFS, or GARDENERS for First-rate Establishments or Single-hand Situations, can be suited, and have full particulars by applying at Stanstead Park and Rutland Park Nurseries, Forest Hill, London, S.E.

E. G. HENDERSON

AND SON have many excellent GARDENERS with approved testimonials for ability now waiting in their Nurseries for re-engagement.

E. G. H. & Son will be pleased to answer any enquiries from Noblemen and Gentlemen requiring such.—Pine-apple Nursery, Maida Vale, London, W.

B. S. WILLIAMS, having at the present time several very excellent GARDENERS upon his Register, is desirous of placing them in Situations where great experience and trust are required. B. S. W. would at the same time beg to intimate that when a Gardener is applied for that the filling of the situation should be left with him, as that would prevent unnecessary correspondence and delay.—Victoria and Paradise Nurseries, Upper Holloway, London, N.

GARDENER (HEAD).—Age 30, married, no family; thoroughly acquainted with all branches of the profession. Good character from last employer.—A. B., Hindon Post-office, Salisbury, Wilts.

GARDENER (HEAD).—Age 30, married; thoroughly competent in all branches of the profession. Four years as Head.—F. T., 2, Berchill Terrace, St. Margaret Road, Hanwell.

GARDENER (HEAD), where two or more are kept.—Thoroughly practical in all departments. Good character from previous employer.—198, Hyde Road, Ardwick, Manchester.

GARDENER (HEAD).—Married, two children (ages 9 and 10); thoroughly competent in the profession. Character and ability satisfactory. Leaving his situation in consequence of the death of his late employer.—H. O., Eford Park, Lynton, Hants.

GARDENER (HEAD).—Age 30; good practical experience in all garden work for the past five years. Has been General Foreman at Rendcomb Park. Good character.—W. THOMPSON, Mr. Lawrence, North Carney, Cirencester.

GARDENER (HEAD).—Age 25, single; steady, energetic, and proficient in the Cultivation of Vines, Peaches, Kitchen Gardening, and the general routine of Gardening. Head Gardener four years.—C. TAGGETT, Ashley Down, near Bristol.

GARDENER (HEAD).—J. RODGERS, for the last three years Gardener to H. S. Lucy, Esq., Charlecot Park, Warwick, and for seven years Gardener to the Honourable E. S. P. Jervis, of Aston Hall, Sutton Coldfield, is at liberty to engage with any Lady or Gentleman requiring the services of a good practical Gardener.—Address as above.

GARDENER (HEAD), age 30.—JAMES PARKER, who is now leaving his present situation as General Foreman, would be glad to communicate with any Lady or Gentlemen requiring the services of a good practical Gardener. Can give good references as to character, abilities, &c.—The Gardens, Saverneke Forest, Marlborough, Wilts.

GARDENER (HEAD).—Age 32; thoroughly understands Early and Late Forcing of Fruit, Flowers, and Vegetables, Stove and Greenhouse Plants, and Flower and Kitchen Gardening. Can be highly recommended. Leaving through death of employer.—W. SEDGLEY, The Gardens, Manor House, Lyndhurst, Hants.

GARDENER (HEAD).—Age 39, married, without encumbrance; thoroughly understands the profession in all its branches. Wife can attend to House during absence of family. Leaving his present employment owing to the breaking up of the establishment. Can have unexceptionable character for last three and a half years. Suburbs of London preferred.—J. C., Guisites Court, Kelvedon, Essex.

GARDENER (HEAD), age 41, married.—A GENTLEMAN wishes to recommend his Head Gardener to any Lady or Gentleman requiring a really useful and practical man; he has had under his charge for three years a considerable quantity of Glass, large Garden, Pleasure Grounds, Park, Plantations, &c.; he is also sober and trustworthy.—M. P., Post-office, Halstead, Essex.

GARDENER (HEAD).—Age 40, married; Scotch; twenty years' practice in Early and Late Forcing, Improvements and Laying-Out Ornamental Planting, Formation of New Grounds, Management of Home Park, Stock, Woods, &c., economically. Twenty years' good recommendations from the Noblemen and Gentlemen he has served in the United Kingdom. Only a moderate remuneration expected.—R., 12, Devonshire Street, West Kensington, W.

GARDENER (HEAD, WORKING).—Age 35, married, one child (age 5); understands Forcing, Flower and Kitchen Gardening, Land and Stock if required. Five years' good character from present employer.—J. GRIGGS, The Gardens, Highlands, Mereworth, near Maidstone, Kent.

To Noblemen and Gentlemen.

GARDENER (HEAD), or GARDENER and FORESTER.—Age 40, married; of varied experience in all kinds of Gardening on a large scale in one of the principal places in England. Seventeen years in last situation. Highest references from last employer.—A. B., Eastington, Cirencester.

GARDENER (HEAD), or GARDENER and BAILIFF—if Gardener alone, where four or five are kept.—Age 40, married, no family; thoroughly understands the profession in all its branches. Sixteen years' good character.—V. Z., Post-office, Bracknell, Berks.

GARDENER (HEAD, or good SINGLE-HANDED).—Age 39, married, two children; understands Forcing, Glass, and Flower and Kitchen Gardening. Good character.—B. C., Post-office, Great Missenden, Bucks.

GARDENER (HEAD, or good SINGLE-HANDED).—Middle-aged, no family; thoroughly understands the profession. Good character.—W. BALL, 1, Hooper Street, Hornsey Road, Upper Holloway, London, N.

GARDENER.—Age 25, married; good knowledge of the profession in all its branches. Good references.—J. L., Post-office, Bletchingley, Surrey.

GARDENER.—JOHN COWAN, The Vineyard, Garston, near Liverpool, would be glad to recommend to any Nobleman or Gentleman requiring a first-class Gardener a Man in the prime of life, who thoroughly understands the profession in all its branches, having had many years' experience in some of the best places in England and Scotland.

GARDENER (SINGLE-HANDED) or Otherwise, or good SECOND).—Age 25, single; thoroughly understands the duties. Twelvemonth's good character.—W. S., 11, Railway Cottages, Tottenham.

GARDENER (SECOND, or good SINGLE-HANDED).—Good character. Reason for leaving, uncomfortable bothy; no objection to a comfortable one. Near Manchester or London.—J. WATTS, Gardens, Bryanston, Blandford, Dorset.

GARDENER (SECOND), in a Gentleman's Garden.—Young, Swiss (French), who desires to improve. Good references. Three years in England.—A. C., 2, Berchill Terrace, St. Margaret Road, Hanwell.

GARDENER (SECOND), in a Gentleman's place, where three or four are kept.—Age 21. Good character. Country preferred. Please state terms.—F. TRILL, 14, Haldane Road, Fulham, S.W.

GARDENER (SECOND), in a good Establishment.—Age 23; 6 years' experience in some of the largest places in England. Good references from present and previous employers.—State particulars to A. B., 11, Holland Street, High Street, Kensington, London, W.

GARDENER (UNDER).—Age 18. Two years' good references.—J. P., Atkinson & Wakein, Booksellers, Alford, Lincolnshire.

GARDENER (UNDER).—Age 20. Four and a half years' good character from the country. Please state wages.—W. G., Mrs. Coater, 6, Princes Street, Bank, E.C.

GARDENER (UNDER), in a Nobleman's or Gentleman's Garden, where he could improve himself in Greenhouse Work.—Age 18; four years' general experience.—Address, stating wages, to WILLIAM GARDNER, 19, Crouch End Hill, Hornsey, N.

GARDENER, and DAIRYWOMAN.—A young Man and his Mother require situations as above noted. Both understand their duties. No encumbrance; family all grown up (the father died eighteen months ago). Can be well recommended.—C. S., 17, Pembury Street, Sittingbourne, Kent.

FOREMAN, in a Nobleman's or Gentleman's Establishment.—Age 24; good experience. First-class references.—G. T., The Gardener's, Well Vale, Alford, Lincolnshire.

FOREMAN, in a Nobleman's or Gentleman's Establishment.—Age 25; eight and a half years' general experience. First-class character from present and previous situations.—W. MARTIN, The Gardens, Elsham House, Grantham.

FOREMAN, in a Nobleman's or Gentleman's Establishment.—Two and a half years in last situation. First-class references.—A. B., 3, Brunswick Road, Upper Holloway, London, N.

To the Trade.

FOREMAN.—Age 26; has had twelve years' good experience in all branches; well up in the Cultivation of Palms, Orchids, and Stove Plants. Good character.—J. B., 13, Alma Terrace, Hammersmith, W.

FOREMAN.—JAMES DUNN, Gardener to Colonel Gascoigne, Parlington, South Milford, Yorkshire, can confidently recommend Henry Wynch, his Foreman, to any Lady or Gentleman who may be in want of a practical and trustworthy Gardener.

FOREMAN (INDOORS), in a Nobleman's or Gentleman's Establishment.—Age 25; well up in Plants and Forcing. Eight years' good reference from previous and present situation.—G. E., Norton, near Daventry, Northamptonshire.

To Nurserymen.

NURSERY FOREMAN, or PROPAGATOR of Roses, Rhododendrons, Fruit Trees, Conifers, &c. Fourteen years' experience in large Nurseries, both in England and Scotland. Highest references. State wages.—W. C., The Rose Nurseries, Car Colston, near Bingham, Nottinghamshire.

To Nurserymen.

FOREMAN (GENERAL, INDOOR), or FOREMAN and PROPAGATOR, in a good-sized Establishment.—A. B., 10, Eslington Street, Grassendale, near Liverpool.

FOREMAN and PROPAGATOR, in a Nursery or good Market Garden.—No incumbrance. Twenty years' experience in London Nurseries. Five years' character. Country preferred.—J. H. WELLS, Ashford Nurseries, near Staines, Middlesex.

To Nurserymen.

PROPAGATOR of General Nursery Stock, could act as FOREMAN.—State wages, &c., to P. Z., 3, Ernest Street, Regent's Park, N.W.

TO NURSERYMEN.—Wanted, by a young Man (age 27) a situation under Glass in a good Establishment. Fourteen years' experience. Good references.—G. S., Swainhill Post-office, near Hereford.

IMPROVER, in the Houses, in a good Establishment.—Age 18. Two years' good character. Would pay a small Premium.—C. H., Mrs. Cloney's, 20, Vackmores, Warwick.

IMPROVER.—The Advertiser can recommend a young Man, 21, four years' experience, to any Gentleman or Head Gardener requiring a trustworthy man.—W. DUNCAN, Newton St. Cyres, Exeter.

IMPROVER.—Wanted, by a young Man (age 20), a situation under the Foreman, where he can improve himself in the Houses. Four years' experience. Can have good references.—Apply, stating full particulars, to A. B., Post-office, Long Ditton, S.W.

GARDENER and STEWARD.—Understands Timber, Repairs, and General Estate Management. Twelve years' high recommendation from last employer.—JOHN KITLEY, Prospect House, Wells Road, Bath.

STEWARD and GARDENER.—Age 36, Scotch, no family; understands the Management of a Gentleman's Estate, and would make himself generally useful in a place of trust.—J. MORGAN, Ainsdale, Southport.

BAILIFF, or GENERAL MANAGER (at Michaelmas or Ladyday).—Age 45; well understood Stock, Woods and Plantations. Has had great experience upon large Estates. Seven years in present situation. Highest references to Noblemen and Gentlemen under whom he has served.—ALPHA, Mr. T. Bowick, Bedford.

SHOPMAN (HEAD).—Age 34; capable of Superintending either a Wholesale or Retail Business. Over twenty years in some of the best Houses in the Trade.—MYOSOTIS, 9, Exchange Street, Norwich.

SHOPMAN.—Age 22; knowledge of Plants and general Nursery Stock; eight years' experience.—ILEX, Mr. Morgan, Arthur Villas, Grove Road, Walthamstow, London.

To the Seed Trade.

SHOPMAN.—Young; good experience and first-class references. Disengaged second week in September.—A. B., Gardener's Chronicle Office, W.C.

To the Seed Trade.

SHOPMAN and TRAVELLER.—Eighteen years' experience of the trade in all its branches. Town or country.—L. W., 79, Bishopsgate Street Within, E.C.

SHOPMAN or TRAVELLER.—Has had upwards of twenty years' experience in some of the leading Houses in the Trade, and can be well recommended.—M. D., Gardener's Chronicle Office, W.C.

To the Seed Trade.

SHOPMAN or WAREHOUSEMAN.—A young Man, with nine years' experience in good Houses, wishes a situation as above. No objection to travel occasionally. Can give first-class references.—R. V., Messrs. Downie & Laird, Seed Merchants, &c., Edinburgh.

To the Seed Trade.

SHOPMAN (ASSISTANT).—Age 22; seven years' experience in England and Scotland. Good character and references.—W. A. C., Post-office, Lintz Green, Gateshead-on-Tyne.

SEEDSMAN (ASSISTANT).—Age 19; four years' experience. Good reference.—W. WEBSTER, Rose Villas, Wavertree, near Liverpool.

KINAHAN'S LL WHISKY. Universally recommended by the Medical Profession. A pure old spirit, mild, mellow, delicious, and most wholesome. Dr. Hassall says, "The samples were soft and mellow to the taste, aromatic and ethereal to the smell. The Whisky must be pronounced to be pure, well-matured, and of very excellent quality."—Wholesale: 20, Great Titchfield Street, London, W.

DINNEFORD'S FLUID MAGNESIA. The best remedy for ACIDITY of the STOMACH, HEARTBURN, HEADACHE, GOUT, and INDIGESTION; and the safest aperient for delicate Constitutions, Ladies, Children, and Infants. DINNEFORD AND CO., 172, New Bond Street, London, and all Chemists.

HOLLOWAY'S OINTMENT and PILLS.—Bowel Complaints, Diarrhoea.—When these Disorders prevail immediate recourse should be had to this Ointment, which should be well rubbed two or three times a day upon the abdomen, and the intestinal irritation will gradually subside. All inflammation will be subdued and excessive action restrained. This treatment, assisted by judicious doses of Holloway's Pills, is applicable to all forms of Diarrhoea and Dysentery attended by Heart Sickness, Griping, Flatulence, and other distressing and dangerous symptoms. After using the Ointment a refrigerant binder should be worn, and the patient should be restricted to a farinaceous diet for a few days till the urgency of the disease has been diminished by the preserving employment of these remedies.

COLORADO BEETLE.

In order to enable our Readers to recognise this Insect should it appear in our Potato Fields, we repeat in this place the illustration given in our last number, at p. 113. The materials for the woodcut were furnished by Mr. ANDREW MURRAY, and were drawn from Nature by Mr. WORTHINGTON G. SMITH.

THE COLORADO BEETLE (NAT. SIZE).

The colour of the larva or grub is reddish or orange, that of the mature Beetle ochre-coloured with ten black stripes running lengthwise down the back. Once the identity of the insect is established beyond doubt, the most rigorous measures must be adopted to prevent its increase and spread. See the *Gardeners' Chronicle* for July 14, p. 38.

SALE BY AUCTION.

Preliminary Notice.

MR. J. C. STEVENS will sell by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., DURING the MONTH of AUGUST, a quantity of RARE PALMS and OTHER PLANTS from (Ghent, including:—Aralia filicifolia, A. gracillima, A. elegantissima, Cocos Weddelliana, Geomoma princeps, Pandanus Pan-chitii, Kentia Lindenii, K. gracilis, Pritchardia filifera, Calamus asperimus, Croton Andreanum, Livistona Hoogendorpii, &c.

To Florists and Jobbing Gardeners.

FOR SALE, a SMALL BUSINESS, in main thoroughfare; very cheap, long lease. Apply, FLORIST, Southampton Street, Camberwell, S.E.

To Nurserymen and Others.

TO BE DISPOSED OF, one of the oldest established NURSERY BUSINESSES in the North of England, with valuable connection.

The executors of the late Mr. John Harrison, of the North of England Nurseries, Catterick Bridge, and Scotton, are open to treat with a gentleman possessing capital, for the disposal of the business, which has an established connection of nearly 50 years.

The Nurseries consist of about 60 acres of Freehold Land, about 40 acres of which are stocked with a choice Collection of Roses and General Nursery Stock. There are good Residences in the Grounds, and fine Ranges of Glass, close to the Catterick Bridge Station of the North-Eastern Railway, situated between Darlington and Richmond, and offering unusual facilities for doing a large and profitable business. A large portion of the purchase money could remain on security of the property at a reasonable rate of interest. Possession could be given at any time as a going concern. Principals or their Solicitors only may apply to the undersigned,

A. E. HARRISON, Solicitor, Church Yard, Rotherham.

Midway between Croydon and Streatham Common.

TO BE LET, a charmingly situate VILLA RESIDENCE, standing in the centre of about 2 Acres of Grounds laid out in Flower and Kitchen Gardens and Croquet Lawn, finely timbered; the House contains three Reception Rooms, six Bedrooms, Bath Room, and usual Offices. There are three Greenhouses, Stabling for Three Horses, Coach House, Man's Room, &c.

Orders to view to be obtained of Mr. NICKERSON, Auctioneer and Surveyor, 121, Cheapside, London, E.C.

Lordine Court, Ewhurst, Sussex.

TO BE LET, for Seven Years, from September 29, 1877, a very convenient RESIDENCE, approached by a Carriage Drive, containing Dining and Drawing Rooms, Office, Kitchen, Scullery, Pantry, Dairy, Cellar, Wine Cellar, Seven Bedrooms, Bath-room, and Three Attics; has Indoor and Outdoor W.C.'s, Well of excellent Water, Rain-water Tank, Wood-room, and Wood Lodge; Hot-house, Greenhouse, Two Pits, very large Garden, well stocked with productive Wall and other Fruit Trees, including Apples, Pears, Plums, Nuts, Peaches, Cherries, &c.; Summer-house, Croquet Lawn, Three-stall Stable, Coach-house, Harness Cup-board, Cow-yard, Lodge, Pigsty, Apple and Store Room, Fencing Shed, and Outbuildings, with or without a Paddock containing 20 or 230.

Lordine Court is situate about 6 miles from Robertsbridge and Battle Stations, and to from Rye.

For further particulars, and orders to view, apply to JAMES COLEMAN VIDLER, Auctioneer and Estate Agent, 26, Havelock Road, Hastings, and (postal address) Magdala House, Rye, Sussex.

THE

IMPROVEMENT OF LANDED ESTATES, BY DRAINAGE, ENCLOSING, CLEARING, and the ERECTION OF FARM BUILDINGS and COTTAGES.

The Land, Loan and Enfranchisement Co.

(Incorporated by Special Act of Parliament)

ADVANCES MONEY:

1st.—To the OWNERS of SETTLED and OTHER ESTATES, for the Erection of Farm Buildings and Cottages, and for the Drainage, Irrigation, Enclosing, Clearing and General Improvement of Landed Property in any part of the United Kingdom.

2d.—To the OWNERS of SETTLED ESTATES in ENGLAND, for the Erection or Completion of Mansions, Stables, and Outbuildings.

3d.—To LANDOWNERS generally, to enable them to subscribe for Shares in Companies for the Construction of Railways and Navigable Canals, which will beneficially affect their Estates.

4th.—To INCUMBERTS, for the Improvement of their Glebe Lands, by Drainage, and the Erection of Farm Buildings and Cottages.

5th.—To COPYHOLDERS, for the Enfranchisement of Copyhold Lands.

The amount borrowed, with the expenses, would be charged on the Estate benefited, and repaid by a rent-charge, terminating in twenty-five years.

No Investigation of the Landowner's Title is necessary. Forms of application, and all further particulars may be obtained of

Messrs. RAWLENCE and SQUAREY, 22, Great George Street, Westminster, S.W., and Salisbury; of Messrs. ASHURST, MORRIS, CRISP, and CO., 6, Old Jewry, London, E.C.; of Messrs. GILLESPIE and PATERSON, W. S., 87a, George Street, Edinburgh, Agents for the Company in Scotland; and at the Offices of the Company, as below.

T. PAIN, Managing Director.

WORTHINGTON SMITH'S

IN SOLUTION.

All PARASITES sink under SALUS IN SOLUTION.

All PLANTS are at once greatly benefited by SALUS IN SOLUTION.

Can be used through the Syringe, Vaporiser, or Watering Pot.

A 14 lb. box of SALUS is sufficient for 100 gals. of water. A 7 lb. box of SALUS is sufficient for 50 gals. of water. A Sample Packet of SALUS is sufficient for 5 gallons of water.

14 lb. for 14s.; 7 lb. for 7s.; Sample by post for 1s. 4d.

SALUS is sold as an excessively fine powder, and can be used in a dry state if desired.

"I feel it a public duty, as well as a personal pleasure of the highest kind, to be able to record this fact, and heartily congratulate Mr. Smith on the success of his SALUS in eradicating the Cucumber and Melon Disease.

"The whole of our plants, old and young, soon got infested with the disease,—they are now in robust health, without speck or spot, and are swelling off and ripening fine crops. "The early Melons, badly affected at one time, are now carrying an enormous load of fine fruit—about a hundred in a small house—so we have reason to be proud of the powers of SALUS and grateful to its discoverer.

"Melons treated with SALUS took the First Prize at the fête of the Suffolk Agricultural Society.

"Our POTATOS were all dressed with SALUS—for the last six weeks their growth has been extraordinary. There is an immense crop of tubers, all sound, in these gardens." D. T. Fish.

"Potatoes are in very good condition. Some little disease has shown itself in the haulm, but we have not found it communicated what to the tubers. I have planted all my crop with SALUS." William Ward, Stoke Edith, Hereford.

ORDERS FOR SALUS

NEW STRAWBERRIES.

JAMES VEITCH & SONS

Beg to announce that they are now prepared to execute Orders for the two following Strawberries, which are offered by them for the first time, and which they can with confidence recommend:—

LOXFORD HALL SEEDLING.

Fruit large and handsome, conical, occasionally flattened and Cockscomb shaped, seeds prominent, skin bright crimson, flesh firm, juicy, and exquisitely flavoured. This is a seedling raised by Mr. Douglas, of Loxford Hall, from a cross between British Queen and La Constante, and retains the rich flavour of the former with the sturdy robust growth and fertility of the latter. Awarded First Prizes at the Metropolitan Exhibitions.

9s. per dozen; 60s. per 100.

PIONEER (Laxton).

Fruit medium-sized, obovate and conical, seeds rather prominent, very dark red, flesh firm, bright red, of a fine brisk rich flavour; plant of very vigorous growth, a great cropper, and very early. Received a First-class Certificate from the Royal Horticultural Society.

9s. per dozen; 60s. per 100.

All other kinds also ready in small pots, and runners from open ground.

DESCRIPTIVE PRICE LIST ON APPLICATION.

VICTORIA and PARADISE NURSERIES,
Upper Holloway, London, N.

SATURDAY, AUGUST 11, 1877.

RICHMOND HILL.

PAINTERS and poets have been busy on this spot for several generations with their brushes, pens, and pencils. Mr. Vicat Cole has recently added a very gorgeous painting to the previously existing store of matter descriptive of the landscape around Richmond Hill. We "hail" the picture cordially. "Hail" is the word which commences several poetical addresses to the Hill, as, for instance, "Hail, fair Parnassus of the British Isles;" "Hail, the hill which boasted Tempé shames!" In the *Heart of Midlothian* there is an unaffected description by a writer who never stood on tip-toe when he wrote, nor "smote a deep-toned shell" as a prelude to English verse. The Duke of Argyll is conducting Jeanie Deans to the touching scene of her interview with Queen Caroline. "After passing through a pleasant village, the equipage stopped on a commanding eminence, where the beauty of English landscape was displayed in its utmost luxuriance. They paused for a moment on the brow of a hill, to gaze on the unrivalled landscape which it presented. A huge sea of verdure, with crossing and intersecting promontories of massive and tufted groves, was tenanted by numerous flocks and herds, which seemed to wander unrestrained and unbounded through the rich pastures. The Thames, here turretted with villas and there garlanded with forests, moved on slowly and placidly."

Such a scene, ever changing in its aspect, must be always new. The Duke was familiar with the spot. He may have thought of the grander hills, the lake and glens of Inverary, but he delighted in Richmond Hill, and had himself a home on the banks of the Thames at no great distance. "This is a fine scene," he said to his companion; "we have nothing like it in Scotland."

Thomson, author of *The Seasons*, had his tree here in the park, and wrote some verses on Richmond. He was a very good poet on subjects that were congenial to his mind, but in tragedy was too comic to be quoted by any but an unkind critic. This is what he says of the purely English landscape—level, rich, and green—which Nature has produced here with the damp, tree and grass-forming brush which she uses in our climate:—

"Thy Hill, delightful Sheen! Here let us sweep
The boundless landscape; now the raptured eye,
Exulting, swift to huge Augusta send;
Now to the sister hills that skirt her plain;
To lofty Harrow now, and now to where
Majestic Windsor lifts his princely brow.

Slow let us trace the matchless vale of Thames,
Fair-winding up to where the Muses haunt
In Twit'nam's bowers, to royal Hampton's pile,
To Clermont's terrass'd heights and Esher's groves.

Enchanting vale! beyond whatever the Muse
Has of Achaia or Hesperia sung."

The reader cannot but feel complimented that the very obliging and polite poet should put on evening costume, and assume a pair of stilts before he begins to sing. The process shows respect for the reader's person, but it does not improve the verse.

As to the "boundless landscape," during a fog you may hear the steamboats puffing down

the river some minutes before they emerge to view, and there is then no boundary between the invisible distance and that which can be seen; but on clear days the furthest horizon lies not much further than Maidenhead. You see from the terrace (or from the top of the "Star and Garter," which adds four storeys to the inconsiderable height of Richmond Hill), Cooper's Hill, St. Ann's Hill, and Windsor; and a few steps further on, within the gateway of the Great Park, St. Paul's comes into view across the level turf.

All the world knows that the view from Richmond Hill is perfect; but it is a short instead of long view, bounded by a low line of hills which rarely exceed 15 to 20 miles distance. Windsor is within 16 miles as the crow flies. The flatness of the country alone gives so low an elevation even such command of landscape as it possesses. Leith Hill and St. Martha's in the same county, and some other sandhills, as well as the chalk ridges between Dorking and Guildford, are higher than Richmond Hill, and command a far wider country, bounded by the South Downs, and far more varied prospect; yet Richmond is unrivalled in the Londoner coming out for the day in June, steeped in the luxury of repose after hard and profitable labour, and enjoying here a double prospect, including the scenery and the lobster salad and champagne which may be obtained in the hotel.

All English landscapes gain by the lights and shadows cast upon the scene by a changing sky. Chobham Ridges in the distance may be sponged out by a passing cloud till the shadow drifts, and tents and troops, and perhaps the raging of a mimic battle, are added to the picture. The curtain is continually falling and rising, and the distant villas or villages are seen and unseen according to the distribution of light and shade, and the "moving accidents" of the "field." The rivers' windings are concealed at this time of year, except for a short distance under the base of the hill, by the thick blind of foliage. The country appears an undulating forest, the eye being placed at too low a level to command the intermediate fields between the woods, the hedgerows, and the copses. An American "guessed the country wanted clearing!"

In one of Mr. Jesse's pleasant volumes he claims for the country which may be seen from Windsor Castle, the spot where three poets have resided—Milton, Pope, and Gray. To these great names two others may be added, including that of Thomson. Charles II., looking towards the spire of Harrow-on-the-Hill from the terrace of Windsor Castle, used to apostrophise it as "the visible church!" We may therefore add Byron, whose connection with the school at Harrow is known to readers of the poet's life. Thomson resided for years in a cottage close to the Queen's Laundry, and looking upon the old Deer Park; and Windsor Castle may be seen from any unobstructed spot near. He wrote *The Seasons* here. His little estate with the large garden came to be called Rosedale from Mr. Ross, who succeeded the poet, and enlarged his residence.

Thirty years ago the house was occupied by Lord Shaftesbury. It has now become a hospital, standing in a garden much diminished in size by the encroachments of dwellings, which now cover the site of the alcove beneath the Chestnut where the poet loved to meditate, and where, as a tablet once informed the visitor, he "sang the seasons and their change." The little old cottage has been enclosed and included in the larger building, as in the case of Mr. Cobden's birthplace. It is believed that the easy habits of an inactive life shortened the poet's days; he died at the early age of forty-eight, of a cold caught on the river, and was buried in the parish church A.D. 1748. *H. Evershed.*

DENDROBIUM AINSWORTHII.

SOME three or four years ago we published a figure, here reproduced (figs. 30 and 31), of this handsome hybrid Orchid, then blooming, we believe, for the first time. Even in this adolescent state it at once secured the award of a First-class Certificate when exhibited at South Kensington. We were greatly pleased and somewhat astonished at the late Whitsontide show at Manchester to see what a splendid specimen this young seedling had formed in so short a space of time. Its appearance as there shown is represented in the annexed engraving from a photograph (fig. 32).

Dendrobium Ainsworthii is certainly one of the most ornamental of the Dendrobies, and one which will be sought after for general cultivation whenever it is obtainable. The white of the sepals and petals, and the rich rosy-purple blotching of the lip, present a most agreeable and pleasing combination, and these high decorative qualities are greatly enhanced by the profusion in which the flowers are produced. We reproduce the original figure for the purpose of contrast, and to show at a glance the progress it has made within so short a period.

A second seedling from the same hatch, called *D. Ainsworthii roseum*, has been flowered, and was exhibited at the Manchester show above alluded to in company with the plant here portrayed. This was noticed in our report of the show in question. It is much in the same way as the original, but has a broader purple spot covering a larger proportion of

FIG. 30.—DENDROBIUM AINSWORTHII (SEEDLING PLANT).

the lip, and is equally handsome and perfectly distinct. Mr. Mitchell may well be congratulated on the success of his hybridising experiment, and Dr. Ainsworth on the possession of two such rare beauties. T. M.

New Garden Plants.

VANDA TESTACEA, *Rehb. fl.*; AERIDES TESTACEUM, *Lindl. Orch.* 238; AERIDES WIGHTIANUM, *Lindl. l. c.*, and *Wall. Cat.*, No. 7320; VANDA PARVIFLORA, *Lindl. B. Reg.* xxx., *Misc.* 57.

There is no doubt that this old species is nearer *Vanda coerulescens*, *Griff.*, than anything else, but it is distinct, however, in the colour of the petals, and the callus on the base of the lip. One might be doubtful as to the oldest name, since *A. testaceum* and *Wightianum* were published with descriptions at the same time. One might say that *Aerides Wightianum*, being a Wallichian name, had the priority. My opinion is that *Wallich's Catalogue* gives no authority for priority, for the names there given have not won sanction by an accompanying description. Let us add that there is already a *Vanda Wightii*, and that *A. testaceum* comes before *A. Wightianum* in Dr. Lindley's book. Those who keep the oldest name given in the genus may write *Vanda parviflora*. This question is a very difficult one. I believe one cannot give an answer for all cases. I feel inclined to believe it best to keep the oldest specific names of the plants for all things published at periods when the limits of genera were not well established. After such an arrangement, I would not acknowledge names recently given in the wrong place. Now the original Lindleyan genus of *Aerides* is very different from what the excellent author thought later to be *Aerides*; and for this reason, I believe, his older species were not so clearly under-

stood, that we could accuse him of a fault when putting the plant under *Aerides*.

I have often undertaken the analysis and have at hand rich materials, including a fresh inflorescence recently sent by Mr. Bull. *H. G. Rehb. f.*

ROOT PRUNING.

ROOT-PRUNING of fruit trees has been so often noticed in your pages that I fear I may be out of place in calling attention to this all-important operation, but as fruit crops are so very light this season there could not be a more favourable opportunity than the present for operating on trees that may require it.

My attention was called to it the other day by a friend writing to ask my opinion about a lot of fruit trees he had taken charge of. His question was, "What shall I do with our Apple and Pear trees? They are as full of gross young wood as Willow trees." Before I notice old neglected ones, I will begin with a few remarks about the planting and training of young ones. I am no advocate for the use of the knife except in the formation of young trees; I prefer regulating their growth by root-pruning—the more we cut the more we get to cut. In large orchards, where the trees are left to take their natural habits, it is very little used.

of the roots, spread them equally over the surface, and cover them with some fresh loam. If the weather is dry I give them a good watering, and level the surrounding soil. As soon as the leaves drop, I have them nicely trained by driving a few stiff pegs into the soil 3 or 4 feet from the stem, then run a wire round the top of them, which is fastened by a few hooks. To this I tie the bottom branches as nearly in a horizontal position as possible. If the trees looked full of wood it is wonderful how this operation seems to lessen their number. If well done they look as if done by an expert in *Azalea* training.

From this time forward give up using the knife, unless you cannot find time to use your finger and thumb. In the course of a few years I again lift the roots back to where I left them at the last lifting, raising them nearer the surface. This periodical root-pruning, if performed early in the season, does not lessen the chances of a crop the following season.

I will now notice the old neglected trees. I would at once carefully remove all superfluous shoots, retaining a few where there was space for them. They generally form nice bearing wood. As soon as sap had risen into the eyes of the cut shoots I would begin root-pruning—the earlier in the season the better, according to the age and strength of the trees. I cut

FIG. 31.—DENDROBIUM AINSWORTHII—FLOWERS, NAT. SIZE.

Young trees for kitchen garden borders and quarters are generally trained as pyramids, and as such I will notice them. When planted, see that they are not planted over deeply, and their roots nicely spread out. Do not use any gross manures, only maiden loam, to give them a good start. Pears on the Quince should be planted out enough to cover the union of the stock and scion. I prune rather closely the first two or three years, according to their respective growths, not to encourage grossness, but to secure sufficient branches to lay the foundation for handsome symmetrical trees. In summer pruning I only remove superfluous laterals. In winter pruning I cut back the leading branches, according to their respective growths, shortening the leader well back to get plenty of lateral branches; I don't summer pinch the laterals of young trees—as for winter pruning, they are generally cut further back than they have brokeo. In bearing trees it is all the pruning required except the regulating of laterals, of which there is no great quantity in well root-pruned trees.

By the end of three or four years they will be getting nice trees, and well furnished with branches to form handsome pyramids. Early in the autumn I have them carefully lifted, open a trench round 3 or 4 feet from the stem, carefully follow the roots to within a short distance of the stem, then return the soil back to within 8 or 10 inches of the surface level, treading it firmly down, then cut any bruised parts

a deep trench round them, deep enough to meet with all their roots; I then have the soil carefully forked away from the roots, following them nearly up to the stem. I find a few pegs useful to peg the roots out of the way of the workmen, so as not to bruise the roots more than possible; they are easier raised to the surface when retained a good length. The soil is now levelled back and well trodden in to within about 15 inches of the surface. I place 3 or 4 inches of good fresh soil on the top of this, then carefully prune all the bruised parts of the roots, spread them nicely on the fresh soil, a person with a spade placing some on the top of them, to keep them in their proper places, and when all is nicely levelled up the work is finished.

I may notice, that if the trees are at all tall, and in an exposed position, it is advisable to root-prune them at twice, two sides one year and the other two the following year, if the check has not been sufficient for a time.

The next time they are root-pruned I dig a trench round them a little further than where I left them at the last, and fork the soil away till I come to the former cuts. I then prune as before, and carefully cover up. It is not well to leave them till they show signs of grossness.

I think the labour bestowed upon them is amply compensated by the return and superior quality of the fruit. It takes very little more time to root-prune than it does to remove the faggot-wood out of them;

besides, in their neglected state they are only worthless cumberers of the ground. I question very much if there is any more useful fruits than good Apples and Pears; many prefer them when in good condition to Grapes and Pines, but when smothered up in dense masses of unnatural foliage they cannot attain either their proper size, colour, or flavour.

To persons about planting I would strongly recommend Apples on the Paradise stock for kitchen garden borders, or where there is but limited space; they are of a dwarf habit, fruit earlier, and do not throw out

of the most useful and interesting plants to be found in the whole vegetable kingdom. Mr. Kurz says his own studies of this group were commenced in the Botanic Gardens, Buitenzorg, Java, many years ago, but owing to the difficulties experienced in procuring the different species of Bamboos growing in British India, and owing to his desire of studying them all in Nature instead of from dried specimens only, he has thought it necessary for the present to treat only of the Bamboos of those countries of which he had the best material at hand, and these are chiefly the

being raised as they are above the ground. They are usually built for a single family only, but the Dyaks of Borneo, like the Naga hill people and other tribes of the eastern frontier of Bengal and the Karens of Burmah, build large communal houses often 200 to 300 feet long by 50 to 100 feet broad. These are divided into as many compartments as there are families, which often amount to 100. Mr. Kurz says:—"I have often seen tays (this is the name by which the communal Karen-houses, or rather villages, are known) which were raised as much as 30 feet from

FIG. 32.—DENDROBIUM AINSWORTHII.

such strong roots. This stock is not generally so much sought after as it deserves to be. E. W.

BAMBOO AND ITS USES*.

THE simple words which constitute the title of this pamphlet form a sufficient foundation upon which might be built a book of much greater extent, and yet Mr. Kurz has managed to say a very great deal, and perhaps all that was necessary to say, on a group

* *Bamboo and its Uses*. By Sulpiz Kurz, Curator, Botanical Gardens, Calcutta. Calcutta; Central Press Company.

Bamboos of the Malayan countries, of which a very fine living collection exists in the botanical gardens of Java.

Under the head of "Uses of the Bamboo Generally" we find a great deal of valuable information, not only the records of the author's own experience, but facts gathered from the writings of other travellers, which the author fully acknowledges. Though the Bamboo is used for almost every purpose in domestic use, its value as a building material is one of the most important. Houses, we are told, that are built in a similar manner to those of the Malays and Burmans are not only of good appearance but are also healthy,

the ground, and when the people therein rushed to one side the whole structure would hang over. One cannot look, then, upon the tay without thinking it in imminent danger of tumbling down, but the elasticity and strength of the numerous supporting Bamboo culms effectually prevent any such accidents. The space under these houses usually is used as sheds for cattle, pigs, fowls, &c. Fishermen often build their houses solely of Bamboo, on Bamboo or Palm poles, far out in the tidal rivers and sheltered bays of the sea, so that they stand in the water up to near the floor with every recurring tide."

For walking-sticks the Malayan and Indian

Bamboos are not so much used as those of Japan, and are derived chiefly from various species of *Arundinaria*. The well-known Japanese Pepper-canes are the produce of a species of *Phyllostachys*. Those of *Phyllostachys nigra* are very elegant and smooth, but have, like a few other of the small kinds of Bamboo, their joints alternately semiterete. Mr. Kurz fully bears out the suggestion made in a paper recently communicated to the Linnean Society and published in its *Journal*, vol. xvi., p. 1, that the jointed walking canes imported from China and known as Whangee canes, and referred to a species of *Phyllostachys*, are the underground and not the aboveground stems. On this point he says:—"In some species of *Phyllostachys* (*P. nigra*) the shoots creep by rhizomes a long way under the ground before their ends come to day, and at the same time they send out lateral shoots from their joints at certain distances, which similarly burst from the ground, and finally grow out into dense shrubs. This species, therefore, covers in a short time large areas by this process, and it is often difficult to check its spread."

On the rate of growth of Bamboos Mr. Kurz enters rather fully, and refers to notes on the subject that have appeared in our own columns. The application of Bamboo for the manufacture of paper is a subject that has created a considerable amount of interest of late, and in the book before us it is pointed out that in China it is the principal material used for this purpose, for which it is cut while it is quite green and then scraped into shavings, the thickest of which are used for stuffing mattresses and pillows and the finer are macerated in water and made into a paste or pulp which is mixed with a certain proportion of isinglass, from which paper of various qualities is made and is of great strength. From these notes it will be seen that for information on the uses of Bamboo this work of Mr. Kurz is a veritable handbook.

THE ROYAL GARDENS, KEW.

(Continued from p. 142.)

EUCALYPTUS.—Hopes still appear to be cherished that the Blue Gum of Tasmania (*E. globulus*) will succeed in the plains of India, and in other tropical countries. This expectation has hitherto, as might have been expected, in every case led to disappointment. A paper by Dr. Brandis "On the Cultivation of the different species of *Eucalyptus* in Northern India," issued by the Indian Government, will no doubt be held conclusive as far as that country is concerned. Dr. Brandis remarks: "It seems to be acknowledged that in the open country in the plains of North India stations are improved and become more healthy by the planting of trees. If this is admitted, then obviously the object desired is gained in the shortest time by planting those species which grow most rapidly." *Eucalypti* are probably not better adapted for this purpose than other quick growing trees, but have the merit of producing very hard timber.

GUTTA-PERCHA.—Literally nothing is known as to the botanical history of the commercial varieties of Gutta-percha. Several kinds of different qualities and even exhibiting different properties are imported into England, and are in immense request, especially in telegraph cable manufactories, but neither the plants which produce them, nor the localities in which they are produced, are approximately known.

Inquiry has been made of us with respect to a gum indifferently known as Pulo-percha, Susu-toko, Pulo-secci, of which small quantities find their way to the London market, and which would be valuable for admixture with other gums for telegraphic purposes. Notwithstanding careful inquiry amongst our correspondents in the Straits Settlements we have failed in tracing its history in any way.

I attach great importance to the prompt investigation of gutta-percha-yielding plants. There is reason to believe that they are very local and restricted in their geographical occurrence. The collection of products of this kind for commercial purposes is shown by experience to inevitably lead to the destruction of the trees producing them, since these are recklessly destroyed, and never replaced. It is not merely, therefore, a matter of scientific interest to ascertain the exact nature of gutta-percha-yielding trees, but it is the first step in securing the perpetuation of the supply. The botanical investigation of a product or plant simply means getting such complete knowledge

about it as to leave no difficulty in the way of recognising it at any time without uncertainty.

LIBERIAN COFFEE.—A strong desire being evinced in Ceylon to ascertain the conditions under which Liberian Coffee is cultivated, in the expectation that it may be successfully grown at a lower elevation than the ordinary Coffee, I had inquiries made both in Liberia and on the Gold Coast, the result of which was communicated to the Ceylon Government. I extract the following statement from the report from Monrovia, as likely to be of more general interest:—

"The Liberian Coffee grows equally well in the immediate neighbourhood of the sea, and at considerable distances from it. Under like conditions of soil and cultivation trees near the seashore in Monrovia are about the same as those at Careysburg, and other places 30 miles distant. The wild Coffee from which the cultivated comes is found at even still greater distance in the interior. Our nearest trees are 100 yards from the sea. At Bassa and Sinon, we are told, trees grow well still nearer the sea."

"Lowest temperature observed at Monrovia, near the sea, 62° Fahr. at 7 o'clock A.M. in the morning of the month of January during the prevalence of the Harmattan winds; highest temperature observed, 91° Fahr. These are exceptional cases. The general temperature ranges from 72° to 87° in the shade. In the country at the farthest point where Coffee is cultivated by the settlers, there is a difference of one or two degrees lower, owing principally to the rise of the land. Along the coast the Coffee tree thrives at only a few feet (say ten) above sea level; at Careysburg and at Mount Coffee it succeeds as well at an elevation of 550 feet."

MELONS FROM TURKESSTAN.—Dr. King forwarded to the Royal Gardens a collection of seeds of the best kinds of Melon grown at Kashgar. These were distributed partly to M. Naudin, the well-known monographer of the Cucurbitaceæ at Collioure, in the South of France, partly to the Royal Horticultural Society at Chiswick. Seeds from kinds which proved the best have been again distributed to several of the best Melon growers in England. They are at any rate likely to give rise to new strains, even if not of themselves of sufficient value for actual horticultural use.

PAPER MATERIALS.—A great demand exists amongst paper manufacturers for abundant and cheap materials for the manufacture of paper. Esparto-grass (*Lygeum Spartum*) when originally introduced for this purpose from Spain was treated with undeserved neglect. Its place is now almost entirely taken by the Alfa of North Africa (*Macrochloa tenacissima*), and both command a high and rising price, while the supply is steadily decreasing. The success of these materials has led to a variety of other vegetable products being brought into notice for the same purpose. Many of these have been sent to Kew for identification, whilst the merits of some have been experimentally tested by T. Routledge, Esq., of the Ford Works, Sunderland.

The following are some of the materials which have come under our notice:—

1. *Bambo.*—This appears to be only really available for paper making when in a young state. The experience, however, of all persons acquainted with tropical vegetation establishes conclusively that cutting the young stems is the most effectual method of destroying the plants. The only possible plan of obtaining paper-material from this source is to cultivate it in the same manner as is pursued for the Sugar-cane, replanting after cutting the crop. Whether under these conditions, and considering the time that would be required before the plants would be mature, the material would allow the paper-maker a profit is extremely doubtful. Added to this, the large amount of water in the young stems would render it necessary to crush and press them in the country where they were grown, and send the "stock" only to this country.

2. *Baobab.*—Paper manufacturers speak with one consent of the magnificent qualities of the bark of this tree. The only drawback to its use is the apparent impossibility of introducing it into the English market in sufficiently large quantities to make it commercially important. Notwithstanding what is stated of the slowness of its growth, I am still of opinion that more might be done in promoting its cultivation in India and other tropical countries.

3. *Fimbristylis spadicea.*—This was the only plant capable of identification out of three proposed paper

materials sent from Vera Cruz. Mr. Routledge thinks they may make "a fair paper."

4. *Heliconia Bihai.*—This is a large Scitamineous plant indigenous in Jamaica and Trinidad, and probably to be procured in considerable quantities. It had been brought under the notice of Mr. Routledge, who was supplied with specimens of the fibre from the museums of the Royal Gardens. He reported that it would "make fair paper."

5. *Lepidosperma gladiatum.*—Paper has been manufactured from this in Australia. It is not considered very promising.

6. *Phragmites communis.*—This well-known British Reed has been imported from Majorca as a paper material. I have no information as to its practical value; it is probably not great.

7. *Uniola virgata.*—A material from Jamaica which we had very great trouble in accurately determining, ultimately proved to be this locally abundant, but otherwise little known grass. Mr. Routledge reports upon it:—

"Altogether the bulky nature of the grass would preclude its coming to England in its raw condition, it might 'faute de mieux' be made into stock in Jamaica. It is not so good for paper making as Esparto, but if Esparto should fail either from scarcity or other causes, it might be something to fall back upon."

POISONOUS GRASS IN KASHMIR.—Dr. Aitchison has sent specimens of a grass poisonous to cattle in Kashmir. It proves to be *Stipa sibirica*, and it is possible that its injurious effects are due rather to the mechanical irritation produced by fragments of the awns than from any noxious principle contained in it. A closely allied species of *Stipa* has been described by Dr. Hance as producing somewhat similar effects in Thibet (*Journal of Botany*, 1876, pp. 210—212).

SUGAR-CANE.—Inquiries have been addressed to me respecting an enormous and apparently little known variety of the Sugar-cane, called the "Elephant Cane of Cochin China," which has been stated to reach a height of 11 feet and a diameter of 7 inches in six months. At my suggestion the Superintendent of the Botanic Garden at Singapore has obtained from Cochin China plants of this cane, which he has succeeded in establishing. I was also indebted to M. Pierre, Director of the Botanic Garden at Saigon, for the following information, which I think may prove interesting to sugar growers in British colonies:—

"This variety is only cultivated for eating or chewing. I do not think it would prove a good sugar-producing cane. . . . But varieties, especially in the case of Sugar-canes, often improve by change of climate. Perhaps this might have the good fortune to succeed better elsewhere. The dimensions as to diameter and height which this variety attains, depends on the length of time during which its growth continues. It requires in a good soil two years to reach 10 feet in height. After five or six years it may reach 16 to 32 feet; such specimens may be seen near native houses, where it is allowed to grow undisturbed as an ornamental plant. In the province of Mythe this variety is cultivated in humid alluvial soils on a considerable scale, but simply for sale in the bazaars and for chewing. It has the peculiarity of possessing a very brittle epidermal layer; so that, instead of becoming pressed out and giving up its juice when passed through the wooden mills employed here, it breaks up into small fragments."

In Demerara the Sugar-canes have suffered from the ravages of the larva of a moth. Mr. McLachlan has been good enough to examine the specimens sent to this country, and he has little doubt that it is identical with the *Phalœna saccharalis* of Fabricius, which is the same as the *Diatrœa sacchari* of Guelding. The ravages of this insect in Mauritius, from which it has perhaps been introduced with canes into the West Indies, are referred to by Westwood in the *Journal of the Linnean Society* (Zoology, vol. 1., pp. 102, 103). The cocoons are spun among the dead leaves of the plant; the best plan of extirpating the insect seems to be an organised system of burning the infested canes, as well as all loose rubbish and leaves in the plantation.

In Queensland the Sugar-cane has suffered much from the attacks of a fungus or "rust." We have received numerous printed communications with respect to it, but from none of these does it clearly appear what the real nature of the fungus may be. This, at least, can probably be ascertained in this country without difficulty, and I am anxious to receive specimens, whether dried or preserved in spirit, which will enable this point to be solved.

{To be continued.}

REPORT ON THE CONDITION OF THE FRUIT CROPS.

[FROM OUR OWN CORRESPONDENTS, JULY, 1877.]

REMARKS ON THE FRUIT CROPS.

We supplement the tabulated report on the present appearance of the fruit crops, which is given in the preceding pages, with the following extracts from communications obligingly sent to us along with such reports. We have placed the counties from which we have received reports in the order of their importance as fruit producing centres, as shown by the Agricultural Returns for 1876, published by the Statistical and Commercial Department of the Board of Trade; which under the head of "Orchards, &c.," gives the acreage of arable or grass lands, used also for fruit trees of any kind. Thus the county of Hereford heads the list with 24,616 acres; Devon coming next with 24,097; and Somerset with 21,029. No other county has an acreage of over 20,000; and there are only three counties which have an acreage of above 10,000 and under 20,000, viz. —Worcester, 14,178; Kent, 11,666; and Gloucester, 11,602. Cornwall stands next with 4372 acres to its credit; followed by Dorset with 3656; Middlesex, 2927; Salop, 2751; and Surrey, 2057. We defer the publication of the remarks which have reached us from other counties, until our next issue.

Hereford.—Fruit trees of all kinds produced a profusion of bloom, but owing to the mildness of the winter, followed by a late spring, sharp frosts prevailing up to the end of May, the trees had no proper rest, and produced a great number of imperfect flowers which could not set. Where fertilisation did
